Figure 5 shows the Fall 2010 groundwater elevation contour map based on monitoring of nested wells along with other selected wells screened in the Model Layer 3. Features that potentially control the regional pattern of groundwater movement in the basins include topographic highs and lows, faults, areas of recharge, and groundwater pumping (discharge). The general direction of groundwater flow is shown by the arrows depicted on Figure 5. Both the Newport-Inglewood Uplift and the Charnock Fault (in the West Coast Basin) are partial barriers to groundwater flow, causing differences in water levels on opposite sides of each fault system; although some subsurface groundwater flows between the Central Basin and the West Coast Basin across the Newport-Inglewood Uplift.

In the Central Basin, groundwater levels are highest in the Montebello Forebay, where the San Gabriel Basin groundwater flows into the Central Basin and significant groundwater recharge occurs. Due to the significant aquifer recharge occurring via the MFSG, there is a mound in the groundwater table and a radial pattern of flow away from the forebay. Groundwater elevations range from a high of about 170 feet above mean sea level (msl) in the northeast portion of the Central Basin above the MFSG in the Whittier Narrows to a low of about 120 feet below msl in the Long Beach area and about 130 feet below msl in the Gardena area (based on the Fall 2010 groundwater elevation contour map, Figure 5). With the exception of the Montebello Forebay and along the WCBB, the majority of groundwater levels in the Study Area are below sea level, which is why continued injection at the seawater intrusion barriers is needed to prevent saltwater intrusion and replenish the basin.

The Los Angeles Forebay historically was recharged by the Los Angeles River, but this recharge has been substantially reduced since the river channel was concrete lined. Groundwater in the Los Angeles Forebay flows generally from east to west toward a pumping depression in the Central Basin Pressure Area. In the Whittier Area, groundwater flows southward from the edge of the Puente Hills into the Central Basin Pressure Area.

In the West Coast Basin, groundwater levels are highest along the WCBB (about 10 feet msl) and decreasing inland reaching the lowest elevation of more than 100 feet below msl near the Newport-Inglewood Uplift (based on the Fall 2010 groundwater elevation contour map, Figure 5). Groundwater flow in the West Coast Basin is generally from west to east. Both the Charnock Fault and Newport-Inglewood Uplift restrict groundwater movement and produce marked discontinuities in groundwater levels.

The groundwater flow patterns, based on the Fall 2010 groundwater elevation contour map (Figure 5), are generally representative of recent and predicted future conditions because managed aquifer recharge operations and groundwater pumping are relatively stable influences on the flow regime. Nonetheless, groundwater pumping in the Central Basin can fluctuate seasonally, as discussed in the next section.

2.8.2 Long-Term Water Level Trends

Figure 5 shows the locations of key wells in the CBWCB, for which long-term records of groundwater levels (hydrographs) are presented in WRD's *Engineering Survey and Report*. These hydrographs depict long-term trends and help monitor overall groundwater conditions in both basins.

As discussed in WRD's *Engineering Survey and Report*, key Well 2S/13W-10A01 is used to represent the overall water level conditions of the Los Angeles Forebay (Figure 26). The maximum water level was measured in 1938 and by 1962 water levels had fallen nearly 180 feet due to basin over-pumping and lack of sufficient natural recharge. Since then, basin adjudication and managed aquifer recharge by LACDPW, WRD, and others have improved water levels in this area by over 80 feet. Over the past 10 years, groundwater levels in this well have remained relatively constant with only minor fluctuations.

Figure 27 shows water levels recorded in six key wells located in the Montebello Forebay. The top chart in Figure 27 shows water levels from three wells located in the northern Montebello Forebay. The middle chart depicts water levels from two wells in the central Montebello Forebay, and the lower chart depicts one well in the southern Montebello Forebay. For some charts, different wells are depicted because some older wells were destroyed or replaced with a newer monitoring point. Operation of the MFSG has had a significant effect on long-term water levels.

Based on available records, groundwater was at its highest levels in the 1940s and reached its lowest levels in the late 1950s due to over-pumping and insufficient natural and managed aquifer recharge. Recharge of recycled water in the Montebello Forebay beginning in the early 1960s and adjudication of the basins have resulted in increased and a general stabilization of groundwater levels. Dips in water level trends since the 1960s are due to drought (lack of local stormwater for recharge) and/or availability of replenishment water (imported water). This condition was observed in 2009 when water levels in some wells in the Montebello Forebay reached a 32-year low. In WY 2009-10, water levels recovered somewhat due to precipitation recharge and availability of imported water for replenishment.

Because groundwater pumping in the Whittier Area is very limited, there are no available wells with a long-term record of groundwater level monitoring. Water level measurements taken since 2000 from the WRD's nested monitoring well Whittier #1 located in the Whittier Area are very stable with little change over the past 12 years.

Figure 28 shows water levels recorded in two key wells located in the Central Basin Pressure Area. Groundwater level highs were measured in these wells in 1935 and then water levels began dropping (over 110 feet) by 1961 due to over-pumping and insufficient natural recharge. Groundwater levels recovered substantially during the early 1960s as a result of replenishment operations in the Montebello Forebay and reduced pumping. Between 1995 and 2007 there have been 100-foot swings in water levels each year from winter to summer. These swings were due to pumping pattern changes by some of the Central Basin water purveyors who operate with more groundwater in the summer months and less groundwater in the winter months, and took advantage of the WRD's In-Lieu Program[3]. However, since May 2007 the in-lieu water has not been made available by MWD, so pumping has remained more constant throughout the year and water levels remain depressed as shown in the two hydrographs in Figure 28.

Figure 29 shows water levels recorded in five key wells located throughout the West Coast Basin. In 1955, the control of groundwater extractions in the West Coast Basin (i.e.,

[3] The basic premise of WRD's In-Lieu Program is to offset the pumping in the basins to lower the annual overdraft and reduce the artificial replenishment needs. The program helps provide an alternate means of replenishing the groundwater supply by encouraging basin pumpers to purchase surplus imported water, when available, instead of pumping groundwater. This can help raise water levels in areas that are otherwise more difficult to address.

adjudication) resulted in the stabilization and reversal of declining water levels in the central area of the basin (top chart in Figure 29), whereas at the southeastern area near the DGB, water levels continued to decline until about 1971, when a recovery began due mostly to the startup of injection at the DGB. For most wells, water levels along the coast have been rising since the early 1970s in response to injection at the seawater intrusion barriers and reduced pumping (USGS, 2003).

2.8.3 Vertical Groundwater Flow

The USGS/GBMP modeling work describes the vertical movement of groundwater between model layers and subareas. Because most (about 80%) of the active groundwater extraction is from the Upper San Pedro (Model Layer 3) aquifers (Table G-2 and Figure 4), vertical groundwater flow directions are downward from Model Layer 1 to Model Layer 2 to Model Layer 3 in all basins and subareas. In the Montebello Forebay, Los Angeles Forebay, Whittier Area, and Central Basin Pressure Area, there is also a downward vertical gradient from Model Layer 3 to Model Layer 4. In the West Coast Basin, the vertical gradient between Model Layer 3 and 4 is mixed depending on the year, but the net vertical gradient is typically upward from Layer 4 to Layer 3. Because of the significant volume of recharge in the Montebello Forebay, there is large horizontal and vertical movement of water emanating from this subarea (USGS, 2003).

2.9 Water Balance

In order to estimate the baseline and future planning period S/N balances in the CBWCB, it is necessary to have an understanding of the associated volumes of groundwater inflow and outflow (i.e., the water balances). The baseline period covers WY 2000-01 to 2009-10, as established in the LARWQCB-approved *SNMP Workplan* (CBWCB Stakeholders, 2011). The future planning period covers WY 2010-11 to 2024-25. A 10-year future planning period was originally established in the *SNMP Workplan,* but the planning period was extended to 15 years through WY 2024-25 at the recommendation of the LARWQCB. The water balance changes from year to year based on a number of factors, including replenishment activities, precipitation, availability of imported water supplies, subsurface inflow and outflow, and groundwater extraction. The difference between the basin inflow and outflow is the change in groundwater storage.

The baseline period water balances provide estimates of specific inflows and outflows for each basin. The various historical groundwater inflows and outflows are reported by WRD in their annual *Engineering Survey and Report* (available on their website: http://www.wrd.org/engineering/groundwater-engineering-reports.php), by the Central Basin and West Coast Basin Watermaster[4] in their annual *Watermaster Service* reports (available on

[4] As a result of the Judgment issued on December 18, 2013, the California Department of Water Resources is no longer Watermaster of the Central Basin. Beginning July 1, 2014, the Watermaster is now comprised of three entities: 1) Administrative Body, 2) Water Rights Panel, and 3) Storage Panel. The Water Replenishment District of Southern California has been designated as the Administrative Body and will be responsible for preparing the annual *Watermaster Service* reports and submitting them to the Water Rights Panel. The Water Rights Panel is

their website: http://www.water.ca.gov/watermaster/aboutwatermaster/index.cfm), and in the USGS/GBMP modeling reports (USGS, 2003; CH2MHILL, 2012b). The baseline and future planning period water balances are discussed in more detail in Appendix D *Baseline and Future Water Balances.*

2.9.1 Groundwater Recharge (Inflows)

Major sources of groundwater replenishment in the Study Area include:

- Managed aquifer recharge in the spreading grounds, instream facilities, and at the seawater intrusion barriers;
- Deep percolation of precipitation;
- Irrigation return flows;
- Percolation of runoff from surrounding uplands (mountain front recharge); and
- Subsurface groundwater inflow from adjacent groundwater basins.

Other minor potential sources of groundwater recharge include leaking pipes, septic systems, and stream losses (not associated with managed aquifer recharge).

The largest volume of recharge in the Central Basin occurs in the Montebello Forebay via the MFSG and instream facilities in the San Gabriel River. Other sources of recharge include injection at the AGB, subsurface inflows, deep percolation of rainfall, irrigation return flows, and mountain front recharge.

Recharge in the West Coast Basin includes injection at the WCBB and DGB, subsurface inflow, deep percolation of rainfall, mountain front recharge, irrigation return flows, and the DGSG.

In the CBWCB, losses from leaking pipes and septic systems are believed to be small in comparison to the major sources. Stream recharge (other than in the Montebello Forebay) is limited, as most streams are concrete lined.

2.9.2 Groundwater Discharge (Outflows)

Groundwater can leave the CBWCB by:

- Pumping/extraction,
- Subsurface outflow to adjacent basins and the ocean, and
- Groundwater discharge to surface water.

Of these, groundwater pumping is the most significant outflow from both the Central Basin and West Coast Basin. Due to the large pumping depressions in both basins, very little groundwater leaves the Study Area as subsurface outflow and while there is some outflow to adjacent areas, the overall net subsurface flow is into the Study Area. Similarly, as discussed above, because

---

ultimately responsible for submitting the final *Watermaster Service* reports to the Superior Court of the State of California for filing.

most streams are concrete lined, there is little opportunity for groundwater discharge to surface water and thus, this source of discharge is assumed to be negligible.

3 Groundwater Quality

In general, groundwater in the main producing aquifers of the CBWCB is of good quality. Localized areas of marginal to poor quality water do exist, primarily at the basin margins where seawater intrusion occurred in the past and also in shallow groundwater near environmental release sites, as discussed further in Section 3.2 *Environmental Release Sites in the CBWCB*.

Between 1900 and the 1950s, groundwater was an important factor in accelerating the urbanization of the CBWCB, which led to increasing demand for groundwater that far exceeded natural freshwater recharge. Excessive over-pumping in the basins caused severe overdraft and created a hydraulic gradient that resulted in seawater intrusion, which contaminated the coastal groundwater aquifers. To address this problem and halt the intrusion, three seawater intrusion barriers were constructed by LACDPW: the WCBB in the mid-1950s, the AGB in the early 1960s, and the DGB in the early 1970s.

While the water injection activities at the barriers were successful in halting further seawater intrusion, these efforts could not address the seawater which had already intruded into the CBWCB before the barriers were constructed. These plumes of saline water, referred to as "saline plumes," are trapped inland of the injection wells, thereby degrading significant volumes of groundwater with high concentrations of chloride and TDS and decreasing the ability of affected aquifers to provide groundwater storage for potable use. These saline plumes are discussed in Section 3.5 *Salt and Nutrient Groundwater Quality*.

Groundwater quality in the CBWCB also reflects current land uses. Environmental release sites are commercial and industrial properties where improper activities (e.g., leaking aboveground and underground storage tanks, leaking pipelines, spills, and illegal discharges, etc.) have contaminated groundwater with localized plumes of petroleum fuels, solvents, and other constituents of concern. In general, these plumes are predominantly limited to shallow groundwater. However, as the aquifers and confining layers in the CBWCB are typically inter-fingered, the quality of groundwater in the deeper production aquifers is threatened by the migration of pollutants from the upper aquifers. This is particularly true in the forebay areas. Environmental release sites in the CBWCB have been or are being investigated/remediated under the oversight of Federal and State regulatory agencies, including the United States Environmental Protection Agency, the LARWQCB, and the California Department of Toxic Substances Control.

TDS, chloride, and nitrate were selected as appropriate representative constituents of salt and nutrients in the CBWCB, as further described in Section 3.1 *Selection of Indicator Parameters of Salt and Nutrients*. The criteria and section process are presented in the following section. Common constituents associated with environmental release sites, special recycled water studies for 1,4-dioxane and n-nitrosodimethylamine (NDMA), and constituents of emerging concern (CECs) are also discussed below.

3.1 Selection of Indicator Parameters of Salt and Nutrients

The LARWQCB-approved SNMP Workplan (CBWCB Stakeholders, 2011) included a list of constituents with Water Quality Objectives (WQOs), per the Basin Plan (LARWQCB, 1994), to be included for discussion in the SNMP. In this SNMP, WQOs are also referred to as Basin Plan Objectives (BPOs). **Table G-6** shows the list of potential constituents[5] for evaluation in the SNMP and the applicable regulatory limit and/or WQO.

To determine the constituents that would be most representative of salt and nutrients in the CBWCB, the following criteria/questions were developed to evaluate the constituents for evaluation in the SNMP:

1. Is the constituent regularly monitored and detected in source waters?
2. Is the constituent a salt or nutrient representative of other salts and nutrients?
3. Is the constituent conservative and mobile in the environment?
4. Is the constituent found in source waters at concentrations above those found in ambient groundwater?
5. Does the constituent have high toxicity for human health?
6. Is the constituent a known contaminant in groundwater in the Study Area?
7. Does the constituent have an effluent limit in a National Pollution Discharge Elimination System (NPDES) permit or a recycled water limit in Waste Discharge Requirements or Water Recycling Requirements issued by the LARWQCB?

Each selected indicator constituent of salt and nutrients is not required to meet all the criteria listed above, but as a group, at least one should meet each criterion. Based on the criteria described above and as further explained below, TDS, chloride, and nitrate are the most representative indicator constituents of salt and nutrients in the CBWCB. In considering constituents of concern, water quality in the MFSG was the primary focus of discussion because it is the largest single source of recycled water recharge in the Study Area.

Other constituents listed in Table G-6 occur naturally in groundwater and typically are not found at elevated concentrations in source waters. TDS, chloride, and nitrate satisfy the indicator selection criteria and are representative of other salts and nutrients. **Table G-7** summarizes the section criteria matrix for TDS, chloride, and nitrate as well as the constituents described in the following sections.

3.1.1 Total Dissolved Solids (TDS)

Total salinity is commonly expressed in terms of TDS as milligrams per liter (mg/L). Because TDS monitoring data are widely available for source waters (both inflows and outflows) in the

[5] Constituents identified in Final Revised Workplan Salt/Nutrient Management Plan (CBWCB Stakeholders, 2011) for preliminary consideration for the SNMP.

CBWCB and because TDS is a general indicator of total salinity, it is appropriate to designate TDS as an indicator for other salts and nutrients.

Table G-6 Regulatory Limits and/or Basin Plan Objectives for Potential Constituents of Concern in Groundwater in the CBWCB

Constituent	Primary MCL	SMCL	Basin Plan Objective	
			Central Basin	West Coast Basin
TDS	NA	1,000 mg/L	700 mg/L	800 mg/L
Sulfate	NA	500 mg/L	250 mg/L	250 mg/L
Chloride	NA	500 mg/L	150 mg/L	250 mg/L
Boron	NA	NA	1.0 mg/L	1.5 mg/L
Nitrate as Nitrate (NO_3)	45 mg/L	NA	45 mg/L	45 mg/L
Nitrate as Nitrogen (NO_3-N) [a,b]	10 mg/L	NA	10 mg/L	10 mg/L
Nitrite as Nitrogen (NO_2-N) [b]	1 mg/L	NA	1 mg/L	1 mg/L
Nitrate plus Nitrite, sum as Nitrogen (NO_3-N + NO_2-N) [b]	10 mg/L	NA	10 mg/L	10 mg/L
Arsenic	10 mg/L	NA	10 µg/L	10 µg/L
Iron	NA	300 µg/L	NA	NA
Manganese	NA	50 µg/L	NA	NA
Color	NA	15 Units	NA	NA
Odor	NA	3 TON	NA [c]	NA [c]

MCL – Maximum Contaminant Level
SMCL – Secondary Maximum Contaminant Level
NA – not applicable
mg/L – milligrams per liter
µg/L – micrograms per liter
TON – Threshold Odor Number
a – MCL based on NO_3-N plus NO_2-N
b – NO_3-N was used to represent nitrogen compounds for the SNMP (see Section 3.1.3 *Nitrate* for discussion)
c – The Basin Plan states, "*Ground waters shall not contain taste or odor-producing substances in concentrations that cause nuisance or adversely affect beneficial uses." (LARWQCB, 1994)*

Table G-7 Salt and Nutrient Selection Criteria

Criteria/Questions	Potential Constituents of Concern in Groundwater for Evaluation in the SNMP										
	TDS	Sulfate	Chloride	Boron	Nitrate-N Nitrate-NO_3	Nitrite-N	Arsenic	Iron	Manganese	Color	Odor
1. Is the constituent regularly monitored and detected in source waters?	X	X	X	X	X	X	X	X	X		
2. Is the constituent a salt or nutrient representative of other salts and nutrients?	X				X						
3. Is the constituent conservative and mobile in the environment?		X		X	X						
4. Is the constituent found in source waters at concentrations above those found in ambient groundwater?			X								
5. Does the constituent have high toxicity for human health?					X	X	X				
6. Is the constituent a known contaminant in groundwater?			X								
7. Does the constituent have an effluent limit in a National Pollutant Discharge Elimination (NPDES) permit or a recycled water limit in Waste Discharge Requirements or Water Recycling Requirements issued by the LARWQCB?	X	X		X	X		X	X	X	X	

TDS – total dissolved solids Nitrate-N – nitrate as nitrogen Nitrate-NO_3 – nitrate as nitrate Nitrite-N – nitrite as nitrogen
LARWQCB – Los Angeles Regional Water Quality Control Board

For the San Jose Creek WRP, the NPDES effluent limit is 750 mg/L (monthly average), based on the BPO[6] for the San Gabriel River watershed (eastern portion of the Study Area [see Figure 20], specifically between Ramona Boulevard and Firestone Boulevard in the City of Los Angeles). In comparison, the recycled water limit for irrigation is 800 mg/L and the limit for recycled water recharged in the Montebello Forebay is 700 mg/L. The Basin-Specific Basin Plan Objective (BSBPO)[7] for TDS in the Central Basin is 700 mg/L and 800 mg/L in the West Coast Basin.

As established by the SWRCB Division of Drinking Water (formerly California Department of Public Health [CDPH]), the Recommended Secondary Maximum Contaminant Level[8] (SMCL) for TDS is 500 mg/L, with an upper limit of 1,000 mg/L and a short-term limit of 1,500 mg/L. While TDS can be an indicator of anthropogenic impacts, there are also natural background TDS levels in groundwater. The background TDS concentrations in groundwater can vary considerably based on purity and crystal size of the minerals, rock texture and porosity, the regional structure, origin of sediments, the age of the groundwater, and many other factors (Hem, 1989). TDS is generally detected below the SMCL of 1,000 mg/L in production wells (i.e. ambient groundwater) in the CBWCB.

Elevated TDS concentrations are undesirable for aesthetic reasons related to taste, odor, or appearance of the water and not for health reasons; however, elevated TDS concentrations in water can damage crops, affect plant growth, and damage municipal and industrial equipment. Reduced salinity (lower TDS concentrations) increases the life of plumbing systems and appliances, increases equipment service life, decreases industrial costs for water treatment, increases agricultural yields, reduces the amount of water used for leaching, reduces brine disposal costs and improves the usability of recycled water (MWD and USBOR, 1999). TDS is conservative and mobile in the environment. Conservative, in this context, means a constituent that does not interact with subsurface media (vadose zone and saturated zone) and therefore, is not readily attenuated in the subsurface.

3.1.2 Chloride

Chloride is an inorganic salt that is naturally-occurring in groundwater and is commonly expressed in terms of mg/L. High concentrations of chloride near the coast may indicate seawater influence. Historical seawater intrusion is a significant groundwater contamination problem in the West Coast Basin and Central Basin. Chloride is the constituent used in the

---

[6] Basin Plan Objectives (BPOs), also referred to as Water Quality Objectives (WQOs), are numerical limits established for various constituents in groundwater. BPOs are set forth in the Basin Plan that was issued by the LARWQCB in 1994 (LARWQCB, 1994).

[7] Basin-Specific Basin Plan Objectives (BSBPOs) are numerical limits unique to a particular basin or subbasin, as set for in the Basin Plan.

[8] A Secondary Maximum Contaminant Level (SMCL) is a water quality standard established by the State Water Resources Control Board, Division of Drinking Water (formerly California Department of Public Health) to manage drinking water for aesthetic considerations, such as taste, color, and odor. Contaminants with only SMCLs are not considered to pose a risk to human health.

CBWCB to provide a general indicator of seawater intrusion and is therefore an appropriate indicator of salt. The chloride concentration of seawater is about 19,000 mg/L.

As established by the SWRCB Division of Drinking Water (formerly CDPH), the recommended SMCL for chloride is 250 mg/L, with an upper limit of 500 mg/L and a short-term limit of 600 mg/L. The BSBPO for chloride is 150 mg/L and 250 mg/L in the Central Basin and West Coast Basin, respectively. Chloride is generally detected below the SMCL of 500 mg/L in production wells (i.e. ambient groundwater) in the CBWCB.

Similar to TDS, elevated chloride concentrations are undesirable for aesthetic reasons related to taste, odor, or appearance of the water and not for health reasons; however, elevated chloride concentrations in water can damage crops, affect plant growth, and damage municipal and industrial equipment. Reduced salinity (lower chloride concentrations) increases the life of plumbing systems and appliances, increases equipment service life, decreases industrial costs for water treatment, increases agricultural yields, reduces the amount of water used for leaching, reduces brine disposal costs and improves the capability to use recycled water (MWD and USBOR, 1999). Chloride is conservative and mobile in the environment. Conservative, in this context, means a constituent that does not interact with subsurface media (vadose zone and saturated zone) and therefore, is not readily attenuated in the subsurface.

3.1.3 Nitrate

Nitrate is a colorless, odorless, and tasteless compound that is present in some groundwater and is commonly expressed in terms of mg/L. Nitrate is a health concern due to methemoglobinemia, or "blue baby syndrome," which affects infants. Elevated levels may also be unhealthy for pregnant women (SWRCB, 2010). High levels of nitrate in groundwater are associated with agricultural activities, septic systems, confined animal facilities, landscape fertilization, and wastewater treatment facilities. Additionally, airborne nitrogen compounds discharged from industry and automobiles are deposited on the land in precipitation and as dry particles, referred to as dry deposition. These sources also contribute to nitrate loading to groundwater.

The fate and transport of nitrogen compounds in the environment is very complex. Nitrate is the primary form of nitrogen detected in groundwater. It is soluble in water and can easily pass through soil to the groundwater table. It can also be added to percolating water through dissolution of formation media. Nitrate can persist in groundwater for decades and accumulate to high levels as more nitrogen is applied to the land surface every year in basins with significant sources of nitrate loading. Nitrate can be removed naturally from water through denitrification.

The BPOs for nitrate and other nitrogen compounds are equivalent to their respective primary Maximum Contaminant Levels[9] (MCLs). Natural nitrate as nitrate (nitrate-NO_3) levels in

---

[9] The primary Maximum Contaminant Level (MCL) is the highest level of a contaminant that is allowed in drinking water and is protective of human health. Primary MCLs are established by the United States Environmental Protection Agency and the State Water Resources Control Board (SWRCB), Division of Drinking Water (formerly

groundwater in the CBWCB, are generally very low (typically less than 10 mg/L as NO_3) and well below the MCL/BPO of 45 mg/L. Nitrate as nitrogen (nitrate-N) plus nitrite as nitrogen (nitrite-N) has an MCL/BPO of 10 mg/L.

Based on this discussion, nitrate-N was selected as the most representative indicator chemical for nitrogen compounds and other nutrients in the CBWCB.

3.1.4 Other Nitrogen Compounds

Table G-6 lists other nitrogen compounds in addition to nitrate-N, and includes nitrate-NO_3, nitrite-N, and nitrate-N plus nitrite-N. Nitrate-NO_3 is equivalent to nitrate-N and a simple calculation can be used to convert one to the other (nitrate-NO_3 = nitrate-N x 4.425). In reviewing the data, it was determined that more of the source water data was reported in nitrate-N, so it was selected as the constituent to represent nitrogen/nutrient loading. In cases where only nitrate-NO_3 data are available, it was converted to nitrate-N for use in the SNMP loading analysis. As nitrate is the primary form of oxidized nitrogen found in groundwater, it was selected to represent all other nitrogen compounds and other nutrients in the CBWCB.

3.1.5 Boron

Boron is a naturally occurring element in soil and groundwater; concentrations depend on the local geology. Other boron sources include industrial waste discharges, particularly from tallow manufacturing. Boron in excess of its Notification Level (NL)[10] of 1 mg/L may have an increased risk of fetal developmental effects, based on studies in laboratory animals.

For the San Jose Creek WRP, the NPDES effluent limit is 1.0 mg/L (monthly average), based on the BPO for the San Gabriel River watershed (eastern portion of the Study Area [see Figure 20], specifically between Ramona Boulevard and Firestone Boulevard in the City of Los Angeles). The limit for recycled water recharged in the Montebello Forebay is 1.0 mg/L, equivalent to the Central Basin BPO. In the West Coast Basin, the BPO for boron is 1.5 mg/L.

The average ambient boron concentration in production wells in the Central Basin Pressure Area[11] (0.9 mg/L, which is just below the BPO of 1.0 mg/L) is slightly higher than the average recycled water concentration of 0.3 mg/L in the effluent of WRPs recharging the MFSG, based on the recent five years of data. Hence, boron detections in the Central Basin Pressure Area are naturally occurring and not related to recycled water recharge. Because of the relatively low

---

California Department of Public Health) and reflect not only the chemicals' health risks but also factors such as their detectability and treatability, as well as the cost of treatment.

[10] Notification levels (NLs) are health-based advisory levels established by the SWRCB Division of Drinking Water (formerly California Department of Public Health) for chemicals in drinking water that lack maximum contaminant levels (MCLs). When chemicals are found at concentrations greater than their notification levels, certain requirements and recommendations apply to water purveyors.

[11] The average concentration in production wells the Central Basin Pressure Area is thought to be most representative of ambient groundwater conditions compared with other areas because the production wells tap the deeper confined aquifers unlikely to be influenced by surface releases from irrigation return flows or managed aquifer recharge from the Montebello Forebay Spreading Grounds or the three seawater barriers.

levels detected in the effluent of WRPs and the comparable but higher average levels observed in groundwater, boron was not designated as an indicator compound for S/Ns in the CBWCB and was not selected for further evaluation in the SNMP.

3.1.6 Arsenic

Arsenic is an element found in the earth's crust and thus, can occur naturally in groundwater. Natural sources of arsenic in groundwater include weathering and erosion of rocks. Groundwater contamination with arsenic can also result from industrial releases from wood preserving, semiconductor manufacturing, petroleum refining, animal feed additives, and herbicide use. Arsenic is classified as a known human carcinogen and also causes other health effects, such as high blood pressure, diabetes, and vascular and skin effects. The primary MCL and accordingly, the BPO for arsenic is 10 micrograms per liter (µg/L).

In WY 2010-11, arsenic was detected at concentrations greater than the BPO in 20% of WRD's nested monitoring wells in the Central Basin and 21% of the nested wells in the West Coast Basin (WRD, 2012). The widespread distribution of arsenic detections indicates it is predominantly naturally occurring as a result of leaching from formation deposits and is unrelated to managed aquifer recharge operations in the CBWCB. Accordingly, arsenic does not appear to be a chemical of concern for recycled water use and groundwater recharge projects as discussed below.

If there is no reasonable potential to exceed the arsenic water quality criterion, wastewater treatment plant NPDES permits (for example, the San Jose Creek WRP NPDES Permit) do not include an effluent limitation for arsenic. In contrast, recycled water permits for groundwater recharge and seawater intrusion barrier projects include arsenic limits based on the MCL/BPO of 10 µg/L. The average ambient arsenic concentration in production wells in the Pressure Area of the Central Basin (13 µg/L, which is above the BPO of 10 µg/L) is greater than the average recycled water concentration of 1.1 µg/L in the effluent of WRPs recharging the MFSG, based on the recent five years of data. Because of the relatively low levels detected in recycled water and the higher concentrations observed in groundwater, it is clear that arsenic is naturally occurring and not the result of recharged recycled water.

In 2011, arsenic was detected in the shallowest aquifer zone (Recent Aquifer) near the AGB at a maximum concentration of 27 µg/L, above the MCL/BPO of 10 µg/L. Since recycled water is not delivered to the Recent Aquifer, this excursion cannot be attributed to recycled water recharge. Since injection of recycled water began at the AGB, arsenic in the Recent Aquifer occasionally has been detected above the MCL/BPO; however, arsenic has not been detected in the water (i.e., blend of recycled and treated imported water) delivered to AGB for injection, nor in the deeper aquifers receiving the injected water. Thus, naturally-occurring arsenic levels in groundwater are higher than the relatively low concentrations detected in recycled water used for recharge.

Based on the discussion above, arsenic was not designated as an indicator compound for S/Ns in the CBWCB and was not selected for further evaluation in the SNMP.

3.1.7 Iron

Iron is a naturally-occurring constituent in groundwater and can also be leached from steel pipes. Elevated iron concentrations can affect the water's suitability for domestic or industrial uses. The SMCL for iron, based on aesthetic concerns, is 300 µg/L. High concentrations of iron in water can stain plumbing fixtures and clothing, encrusts well screens, clogs pipes, and may affect taste and odor. It is considered an essential nutrient for human health and does not pose significant health effects except in special cases. Some industrial processes cannot tolerate more than 100 µg/L of iron in water. Iron is occasionally detected in production wells (i.e. ambient groundwater) in the CBWCB at concentrations above the SMCL.

If there is no reasonable potential to exceed the iron water quality criterion, NPDES permits do not include an effluent limitation for iron (for example, the San Jose Creek WRP NPDES Permit). In contrast, recycled water permits for groundwater recharge and seawater intrusion barrier projects include iron limits based on the SMCL. The average iron concentration in production wells in the Pressure Area of the Central Basin[10] (131 µg/L, which is significantly below the SMCL of 300 µg/L) is higher than the average recycled water concentration of 97 µg/L in the effluent of WRPs recharging the MFSG, based on the recent five years of data. Thus, iron detections in groundwater are naturally occurring and not related to recycled water use or recharge.

Because the iron concentrations in recycled water are lower than the average concentration in ambient groundwater, iron was not designated as an indicator compound for S/Ns in the CBWCB and was not selected for further evaluation in the SNMP.

3.1.8 Manganese

Manganese is a naturally occurring constituent in groundwater. The SMCL for manganese, based on aesthetic concerns, is 50 µg/L. Similar to iron, elevated manganese concentrations are objectionable in water. Manganese in water can cause black staining of fixtures and laundry and affect taste and odor. Like iron, manganese is considered an essential nutrient for human health. Manganese is sometimes detected in production wells (i.e. ambient groundwater) in the CBWCB at concentrations above the SMCL.

Recycled water permits for groundwater recharge and seawater intrusion barrier projects include manganese limits based on the SMCL. The average manganese concentration in production wells in the Pressure Area of the Central Basin[10] (88 µg/L, which is greater than the SMCL of 50 µg/L) is higher than the average recycled water concentration of 13 µg/L in the effluent of WRPs recharging the MFSG, based on the recent five years of data. Hence, elevated manganese detections in the CBWCB are naturally occurring and not related to recycled water use or recharge.

Because of the relatively low manganese levels detected in recycled water and the fact that the concentrations in groundwater are higher than in recycled water, manganese was not designated as an indicator compound for S/Ns in the CBWCB and was not selected for further evaluation in the SNMP.

3.1.9 Color

Many constituents found in water can affect the color. Colored water is often the result of natural conditions (e.g., from plants and minerals) or from rusty pipes or air entrainment. Color is primarily an aesthetic concern, so it has a SMCL of 15 units. Groundwater samples from production wells in the CBWCB frequently exceed the color SMCL.

Color does not have an NPDES effluent limit. Recycled water permits for groundwater recharge and seawater intrusion barrier projects include color limits based on the SMCL (although the groundwater replenishment permits issued to SDLAC in 2011 have eliminated color from the list of regulated constituents[12]). The average color measurement in production wells in the Pressure Area of the Central Basin[9] (16 units, which is just above the SMCL of 15 units) is higher than the average recycled water measurement of 10 units in the effluent of WRPs recharging the MFSG, based on the recent five years of data. Hence, elevated color levels in the CBWCB are naturally occurring and not related to recycled water use or recharge.

Because the color levels in recycled water are lower than in ambient groundwater, color was not designated as an indicator compound for S/Ns in the CBWCB and was not selected for further evaluation in the SNMP.

3.2 Environmental Release Sites in the CBWCB

Environmental release sites are commercial and industrial properties where improper activities (e.g., leaking aboveground and underground storage tanks, leaking pipelines, spills, illegal discharges, etc.) have contaminated groundwater with localized plumes of petroleum fuels, solvents, and other hazardous substances. In general, these plumes are predominantly limited to shallow groundwater. However, as the aquifers and confining layers in these alluvial basins are typically inter-fingered, the quality of groundwater in the deeper production aquifers is threatened by the migration of pollutants from the upper aquifers. This is particularly true in the Forebay areas. Environmental release sites in the CBWCB have been or are being investigated/remediated under the oversight of Federal and State regulatory agencies, including the United States Environmental Protection Agency (USEPA), the LARWQCB, and the California Department of Toxic Substances Control (DTSC).

Figure 30 shows all active and inactive environmental release sites in the Study Area, including land disposal sites, military sites, cleanup program sites, and active or proposed Superfund sites. Active sites refer to properties currently being investigated or cleaned up under regulatory agency review or oversight. Inactive sites indicate cases that have been closed by the relevant regulatory agency. As shown in Figures 30 and 31, there are thousands of environmental release sites in the Study Area. Nonetheless, relatively few sites have impacted deeper water supply aquifers in the CBWCB.

For Superfund sites and active land disposal sites, call-out boxes show the name of the site and the main constituents of concern (COCs). Chemicals commonly associated with the environmental release sites in the CBWCB are trichloroethylene (TCE), tetrachloroethylene

[12] Information provided by Monica Gasca, SDLAC.

(PCE), metals, perchlorate, and hexavalent chromium. While 1,4-dioxane is not identified as a COC at any contaminated sites listed in the SWRCB's Geotracker online database (http://geotracker.waterboards.ca.gov/), 1,4-dioxane is known to be a COC at some environmental release sites. Figure 31 shows active and inactive leaking underground storage tank (LUST) sites. The primary COCs associated with LUST sites are petroleum hydrocarbons and gasoline additives, including benzene, toluene, ethylbenzene, xylenes, and methyl tertiary butyl ether (MTBE).

In an effort to minimize or eliminate threats to groundwater supplies, WRD established the Groundwater Contamination Prevention Program. As part of this program, WRD created and administers the CBWCB Groundwater Contamination Forum, a data-sharing and discussion forum with key stakeholders that include the United States Environmental Protection Agency (USEPA), California Department of Toxic Substances Control (DTSC), LARWQCB, CDPH (now the SWRCB Division of Drinking Water), USGS, and various cities and drinking water purveyors. In 2005, these stakeholders drafted and signed a Memorandum of Understanding, agreeing to meet regularly and share data on groundwater contaminated sites within the CBWCB. As a key stakeholder, WRD has been tracking and working in close consultation with the regulatory agencies to provide data and technical support to expedite investigations and cleanups at priority groundwater contaminated sites within the CBWCB.

Priority environmental release sites in the CBWCB were selected by WRD, with input from the other members of the CBWCB Groundwater Contamination Forum, based on certain criteria such as hydrogeology, depth and concentration of the contaminants, fate and transport of the COCs, distance to nearby water supply wells, presence of contaminated drinking water wells in the site vicinity, proximity to recharge areas, and status of site characterization/remediation. **Table G-8** is a list of WRD's current priority groundwater contaminated sites, principle constituents of concern, and weblinks to where information regarding these sites can be found in online agency databases that are accessible to the public**.** Figure 32 provides the locations of these sites and the associated index number indicated in Table G-8. Sites are continuously added or removed from WRD's list based on ongoing evaluations of the criteria.

Currently, WRD monitors many contaminants (as well as salt and nutrients) in over 300 nested wells at more than 55 locations throughout the CBWCB and compiles and evaluates the data and Title 22 water quality data from production wells as part of their annual *Regional Groundwater Monitoring Reports*, which are available for downloading from the WRD website (http://www.wrd.org/engineering/groundwater-engineering-reports.php). Each of WRD's nested wells are screened in a specific aquifer. This monitoring and reporting is part of WRD's mission to preserve groundwater quality in the CBWCB.

VOCs - volatile organic compounds
SVOCs - semivolatile organic compounds
TPH - total petroleum hydrocarbons
RWQCB - Regional Water Quality Control Board
DTSC - Department of Toxic Substances Control
USEPA - United States Environmental Protection Agency
a - Sites are listed in alphabetical order, with the exception of Site No. 49

Contamination from environmental release sites is generally localized and limited to shallow aquifers. The fate and transport of the constituents associated with these sites is dependent on local site-specific characteristics such as lithology. Typically, the volumes of chemicals released from contaminated sites are not known and cannot be accurately estimated. Also, the timing and duration of the releases are typically unknown. Therefore, loading analyses for these sites and associated COCs are infeasible. As stated earlier, environmental release sites in the CBWCB are actively investigated, monitored, and remediated under existing programs managed by the LARWQCB, DTSC, USEPA, and other local regulatory agencies. Accordingly, detailed analysis of releases and loading from contaminated sites was not conducted as part of the SNMP. However, a brief overview discussion of key chemicals associated with environmental release sites is provided below, largely based on WRD's *WY 2010-2011 Regional Groundwater*

Monitoring Report (WRD, 2012), as well as databases/websites maintained by regulatory agencies, including the LARWQCB, DTSC, and USEPA.

3.2.1 Trichloroethylene (TCE)

TCE is a solvent used in metal degreasing, textile processing, and dry cleaning. Because of its potential health effects, it has been classified as a probable human carcinogen. TCE contamination is associated with point sources and is not widely detected in groundwater in the CBWCB at concentrations above the primary MCL of 5 µg/L. In 2010-11, TCE was below the MCL in 90% of WRD's nested monitoring wells in the Central Basin and 95% of the nested wells in the West Coast Basin. No Central Basin or West Coast Basin nested wells screened in the Silverado Aquifer, the main producing aquifer in the Study Area, contained a detectable TCE concentration in 2010-11 (WRD, 2012).

For production wells sampled between 2008 and 2011, TCE was mostly undetected or detected below the MCL in most wells located in the CBWCB. Of the 279 CBWCB production wells that were sampled, only 17 wells contained TCE above the MCL; these wells are located in the northern portion of the Central Basin, within or near the Montebello Forebay and Los Angeles Forebay. TCE was not detected in any production wells located in the West Coast Basin (WRD, 2012).

3.2.2 Tetrachloroethylene (PCE)

PCE is a solvent used commonly in the dry cleaning industry, as well as in metal degreasing and textile processing. Like TCE, PCE is a probable human carcinogen. During 2010-11, PCE was not detected above its primary MCL of 5 µg/L in any of WRD's nested monitoring wells in the CBWCB.

For production wells sampled between 2008 and 2011, PCE was mostly undetected or detected below the MCL in most wells located in the CBWCB. Of the 279 CBWCB production wells that were sampled, only 17 wells contained PCE above the MCL; these wells are located in the northern portion of the Central Basin, within or near the Montebello Forebay. PCE was not detected in any production wells located in the West Coast Basin (WRD, 2012).

3.2.3 Perchlorate

Major sources of perchlorate contamination in California groundwater include facilities manufacturing rockets, missiles, road flares, and fireworks. Perchlorate contamination of groundwater has also been attributed to the use of Chilean fertilizer. Perchlorate can occur naturally in the environment; although, typically at very low concentrations. Perchlorate is rarely detected above its primary MCL of 6 µg/L in WRD's monitoring wells or production wells within the CBWCB (WRD, 2012). However, perchlorate has been detected at elevated concentrations in groundwater beneath some contaminated sites located in the Los Angeles Forebay.

3.2.4 Hexavalent Chromium

Hexavalent chromium, along with trivalent chromium, are two forms of the metal chromium. Together, these forms of chromium are designated as "total chromium." Hexavalent chromium is a known carcinogen, while trivalent chromium is much less toxic. The respiratory tract is the major target organ for hexavalent chromium toxicity. Both forms of chromium occur naturally in groundwater and are also introduced to soil and groundwater through disposal practices from commercial and industrial operations.

The primary MCL for hexavalent chromium is 10 μg/L; the total chromium MCL is 50 μg/L. Groundwater monitoring in WY 2010-11 indicated that relatively low concentrations of hexavalent chromium, below 5 μg/L, are generally widespread and observed in many of WRD's nested monitoring wells throughout the CBWCB, likely the result of naturally-occurring conditions. Concentrations detected above 5 μg/L were limited to the shallowest zones at three Central Basin and one West Coast Basin nested well locations. Hexavalent chromium was not detected above the MCL in any CBWCB production wells sampled between 2008 and 2011 (WRD, 2012).

3.2.5 1,4-Dioxane

1,4-Dioxane is used primarily as a solvent in the manufacture of chemicals and as a laboratory reagent. It is frequently found at contaminated sites where 1,1,1-trichloroethane (1,1,1-TCA) was used for degreasing. 1,4-Dioxane is also a trace chemical found in cosmetics, detergents, and shampoos. It is highly soluble and mobile in groundwater. On November 22, 2010, the CDPH (now the SWRCB Division of Drinking Water) revised the NL for 1,4-dioxane from 3 μg/L to a more stringent NL of 1 μg/L, to reflect an update in the risk analysis announced by the USEPA in August 2010.

For production wells sampled between 2008 and 2011, 1,4-dioxane was mostly undetected or detected below the NL in most wells located in the CBWCB. Of the 238 CBWCB production wells that were sampled, 45 wells contained 1,4-dioxane above the NL. 1,4-Dioxane was not detected in any production wells located in the West Coast Basin. The SWRCB's Geotracker database identified no contaminated sites with 1,4-dioxane as a primary COC. It is likely that additional sites with 1,4-dioxane as a COC would be identified if individual site data and reports were compiled. Nonetheless, 1,1,1-TCA was identified as a COC at 16 sites in the Central Basin and 4 sites in the West Coast Basin, indicating the potential for 1,4-dioxane contamination.

As discussed in Section 3.3.2, special recycled water studies of 1,4-dioxane in the CBWCB, conclude that it is not likely that recycled water is a source of 1,4-dioxane in groundwater. Because detections in groundwater are widespread, it is likely the result of numerous point source environmental release sites and not likely associated with recycled water use or recharge.

3.3 Special Recycled Water Studies

Multiple special studies associated with recycled water and its influence on groundwater have been conducted in the CBWCB. The SDLAC has conducted extensive studies of the fate and transport of NDMA near its WRPs and in the Montebello Forebay. SDLAC also prepares data tables summarizing the concentrations of NDMA and 1,4-dioxane in recycled water and monitoring wells in their *Montebello Forebay Groundwater Recharge Annual Monitoring*

Reports. WRD has also conducted a special study of 1,4-dioxane in groundwater in the CBWCB. Below is a further discussion of each of these studies and chemicals.

3.3.1 N-Nitrosodimethylamine (NDMA)

High levels of NDMA in groundwater in California is typically related to the disposal of liquid rocket fuels associated with the aerospace industry. NDMA is also generated as a byproduct of wastewater treatment, in particular disinfection using chloramines. NDMA is a probable human carcinogen. It has no MCL, but has a NL of 10 nanograms per liter (ng/L). NDMA has been detected in recycled water used for recharge at the MFSG at concentrations above the NL. Nonetheless, it has rarely been detected in monitoring or production wells in the Montebello Forebay due to its significant attenuation in surface water during transport to the spreading grounds through ultraviolet irradiation (UV) exposure and soil aquifer treatment (SAT) as the water percolates through the top most inches of soil and the vadose zone. The SDLAC previously conducted a comprehensive multi-year study of NDMA fate and transport at the Montebello Forebay (Kennedy/Jenks/Todd, 2008). The study found that NDMA in recycled water is significantly attenuated through the following processes: 1) in surface water likely through UV attenuation processes as the water travels from the WRP effluent discharge locations to the spreading grounds and 2) through soil aquifer treatment (likely bioattenuation processes) in the subsurface. The study concluded that NDMA in recycled water recharged at the MFSG does not impact nearby water supply wells.

3.3.2 1,4-Dioxane

Regulations for groundwater replenishment using recycled water (California Code of Regulations, Title 22, Division 4, Chapter 3, Articles 5.1 and 5.2) specify that tests for 1,4-dioxane can be used to demonstrate a sufficient oxidation treatment process for full advanced treatment of recycled water. While 1,4-dioxane monitoring is not required in the permit for groundwater recharge at the MFSG, the SDLAC has been conducting semiannual monitoring of the effluent from the San Jose Creek, Pomona, and Whittier Narrows WRPs as part of NPDES requirements. Since the SDLAC began 1,4-dioxane monitoring in 2002, the annual average concentrations at these WRPs have ranged from 1.1 to 2.0 µg/L and have been consistently below the former 1,4-dioxane NL of 3 µg/L (SDLAC, 2011). The current NL is 1 µg/L.

In May, June, and July 2011, the SDLAC monitored effluent samples at the San Jose Creek, Pomona, and Whittier Narrows WRPs as part of a 3-month study to investigate the occurrence of 1,4-dioxane in the influent and its fate through the WRP treatment processes. There appears to be a consistent low level of 1,4-dioxane in all WRP effluent. Previous research indicated that samples collected over a 2-year period during the *Montebello Forebay Attenuation and Dilution Study* (Kennedy/Jenks/Todd, 2008) showed no detections of 1,4-dioxane at the spreading grounds headworks or production wells. There was only one detection in a shallow monitoring well at a concentration of 1.5 µg/L.

Another regional groundwater investigation conducted by WRD in the Montebello Forebay during 2002 through 2003 showed that 1,4-dioxane was not detected in any of its routinely monitored nested monitoring wells or production wells, except in one production well. 1,4-Dioxane appears to be reduced during river transport of recycled water from the WRPs to the spreading grounds and during percolation. Therefore, it is not likely that recycled water is a source of the widespread detections of 1,4-dioxane in groundwater in the Study Area. Because 1,4-dioxane is almost never detected in groundwater near the MFSG, widespread detections in groundwater are likely the result of point source environmental release sites.

3.4 Constituents of Emerging Concern (CECs)

CECs generally have no established water quality standards or NLs. These chemicals may be present in various waters at very low concentrations and are now detected as the result of more sensitive analytical methods. Information regarding their health significance is evolving with the development of acceptable daily intake levels and drinking water equivalent levels; however, information is lacking on the full spectrum of potential CECs and their health significance in mixtures. CECs include several types of chemicals, such as (i) pesticides, (ii) pharmaceuticals and ingredients in personal care products, (iii) veterinary medicines, (iv) endocrine disruptors, and others.

A Science Advisory Panel (Panel) was formed to identify a list of CECs for monitoring recycled water used for groundwater recharge and landscape irrigation. The Panel completed its report titled, "Monitoring Strategies for Chemicals of Emerging Concern (CECs) in Recycled Water – Recommendations of a Science Advisory Panel," (Panel Report; http://www.waterboards.ca.gov/water_issues/programs/water_recycling_policy/docs/cec_monitoring_rpt.pdf) on CECs in June 2010 and recommended monitoring of selected health-based and treatment performance indicator CECs and surrogates in recycled water used for groundwater recharge projects. No CEC monitoring was recommended for landscape irrigation due to the low risk for ingestion of the water. The CEC monitoring recommendations were directed at surface spreading using tertiary-treated recycled water (specifically, recycled water and groundwater monitoring) and injection projects using recycled water that has undergone reverse osmosis and advanced oxidation (specifically, recycled water monitoring). The Panel did not address or make recommendations related to CEC monitoring for SNMPs.

Draft amendments to the SWRCB's Recycled Water Policy were released in May 2012, September 2012, October 2012 (SWRCB hearing change sheets), and January 2013. The May 2012 draft amendment proposed, in accordance with the Panel's recommendations, 1) monitoring requirements for CECs and surrogates in recycled water used for groundwater recharge; and 2) a reduction of priority pollutant monitoring of recycled water used for landscape irrigation. In the September and October 2012 draft amendments, language was included that provided three exceptions for Regional Water Quality Control Boards to impose additional CEC monitoring requirements: 1) if recommended by CDPH (now the SWRCB Division of Drinking Water); 2) if requested by a project sponsor; and 3) required in an adopted SNMP. Stakeholders submitted written comments to the SWRCB asking that until such time as a SWRCB expert panel specifically makes recommendations regarding CEC monitoring for SNMPs, this issue should be left to stakeholders preparing SNMPs and the Basin Plan amendment process. In response, the SWRCB deleted exception No. 3. The Recycled Water Policy Amendment was adopted by the SWRCB on January 22, 2013 and was approved by the Office of Administrative Law on April 25, 2013.

Regulations regarding groundwater replenishment (both surface and subsurface applications) using recycled water are specified in California Code of Regulations, Title 22, Division 4, Chapter 3, Articles 5.1 and 5.2. These regulations establish monitoring requirements for indicator compounds that will be selected by the project sponsor based on several factors, including the indicator compound's ability to characterize the presence of CECs. Project sponsors must conduct studies at initial operation of the groundwater recharge project and at 5-year intervals thereafter to determine the occurrence of indicator compounds in the recycled water. The protocol for the occurrence study, the study's results, and the indicator compounds to be monitored shall be reviewed and approved by the SWRCB Division of Drinking Water (formerly CDPH).

The LARWQCB has taken actions to begin to address CECs and has begun to include requirements for CEC Special Studies in NPDES permits for Publicly Owned Treatment Works (POTWs) in the region. The development of a CEC monitoring strategy for the region was identified as a priority project during the project selection phase of the 2011-13 Basin Plan triennial review. The SDLAC has begun monitoring effluent for CECs at the water reclamation plants that supply recycled water to the Central Basin. For the West Coast Basin, there are no POTWs that discharge to inland surface water. CEC monitoring requirements have been included in permits issued for the injection of recycled water at the AGB, DGB, and WCBB. The list of CECs is based on prior versions of the CDPH (now the SWRCB Division of Drinking Water) draft groundwater recharge regulations (designated as the Endnote 5 compounds).

The USGS (2009) has conducted some groundwater monitoring for CECs in the CBWCB under the Groundwater Ambient Monitoring and Assessment (GAMA) program (http://pubs.usgs.gov/ds/387/). No CECs were detected at concentrations higher than health-based thresholds. In addition, the Southern California Coastal Water Research Project (SCCWRP) with the David and Lucile Packard Foundation has sponsored an expert panel to provide the State with recommendations on appropriate monitoring and management strategies for CECs to limit the impact of CECs on oceans, estuaries and coastal wetlands, and freshwater ecosystems (SCCWRP, 2012). To vet the initial recommendation from the expert panel, SCCWRP is developing a proposed CEC pilot surface water monitoring plan to address which CECs to monitor, where and how often they should be monitored, and quality assurance/quality control guidelines. The draft plan will be reviewed by the expert panel and stakeholders in Spring 2014 with a goal of finalizing the plan by the end of 2014. Once finalized, 3-year pilot monitoring programs will be conducted at 6 locations throughout the State. The expert panel and stakeholders will review the data from the pilot monitoring and will develop recommendations for NPDES surface water-specific CEC monitoring programs.

The SWRCB Recycled Water Policy states, *"Each salt and nutrient management plan shall include . . . [a] provision for annual monitoring of Emerging Constituents/Chemicals of Emerging Concern (e.g., endocrine disruptors, personal care products or pharmaceuticals) (CECs) consistent with recommendations by CDPH and consistent with any actions by the State Water Board taken pursuant to paragraph 10(b) of this Policy."* (SWRCB, 2009). Existing monitoring for CECs, as well as special studies that are investigating CECs, are discussed in detail in Appendix K *Monitoring Plan* of the SNMP. As discussed further in Appendix K of the SNMP, monitoring for CECs in the Study Area is being conducted for the groundwater recharge projects that utilize recycled water, wastewater treatment plants that discharge to surface water, and for special studies. There are also ongoing leading edge research efforts to further develop analytical methods and understand the health implications of low level detections of CECs. As such, no additional CEC monitoring was found to be warranted in the CBWCB and thus, not proposed as part of the SNMP Monitoring Program.

3.5 Salt and Nutrient Groundwater Quality

As discussed in Section 3.1, TDS, chloride, and nitrate-N were selected as the most appropriate indicators of S/Ns in the CBWCB. These three constituents were used to characterize existing S/N groundwater quality and assimilative capacities of the basins.

BPO/BSBPOs for the CBWCB were established by the LARWQCB and are provided in Chapter 3 of the Basin Plan (LARWQCB, 1994). The BPO/BSBPOs for TDS, nitrate-N, and chloride are listed in **Table G-9**. There are BSBPOs for TDS and chloride in the Central Basin and West Coast Basin and a single BPO for nitrate-N in both basins.

The BPO and BSBPOs are the criteria used to evaluate the existing assimilative capacity of the CBWCB. The existing assimilative capacity is the difference between average groundwater quality and the BPO/BSBPO.

Table G-9 Water Quality Objectives for Salt and Nutrients in Groundwater in the CBWCB

Indicator Constituent for Salt and Nutrients	Central Basin	West Coast Basin
TDS	700 mg/L	800 mg/L
Chloride	150 mg/L	250 mg/L
Nitrate as Nitrogen (NO_3-N)	10 mg/L	10 mg/L

Source: LARWQCB Basin Plan
mg/L – milligrams per liter

3.5.1 TDS, Chloride, and Nitrate Fate and Transport

Fate and transport describes the way a salt or nutrient move through an environment or media. Groundwater flow directions and rates, the characteristics of the constituent, and the characteristics of the aquifer determine fate and transport of any given constituent. Vertical and horizontal groundwater flow direction and velocity were described in Section 2.9 *Water Levels and Flow.*

S/Ns in source waters recharging the CBWCB may be increased through use and movement through the vadose zone and aquifer. This can occur through fertilizer use, which adds nitrogen that is not completely removed by plant uptake. S/Ns in irrigation water can also be concentrated by evapotranspiration (ET). Additionally, dry deposition, the process by which airborne pollutants are deposited to the earth, can contribute to increased S/Ns in percolating water. As precipitation and irrigation water infiltrates, S/Ns in the shallow soils can be picked up from the surface soils. S/Ns also exist in subsurface materials and can be leached via dissolution as water percolates.

Some S/Ns, such as TDS and chloride are considered conservative in that they are not readily attenuated in the environment. In contrast, processes that affect the fate and transport of nitrogen compounds are complex, with transformation, attenuation, uptake and leaching in various environments. Nitrate is the primary form of nitrogen detected in groundwater. It is soluble in water and can easily pass through soil to the groundwater table. Nitrate can persist in groundwater for decades and accumulate to high levels as more nitrogen is applied to the land surface every year.

Assumptions regarding fate and transport processes and potential chemical reaction rates for S/Ns are described in Appendix I *Simulated Baseline and Future Salt and Nutrient Groundwater Quality*.

3.5.2 Water Quality Analysis Methodologies

The methodologies used to calculate average groundwater quality and assimilative capacity are described in this section.

3.5.2.1 Subareas/Layers for Water Quality Assessment

In addition to the water quality assessment of each of the basins as a whole, the Central Basin was divided into distinct hydrogeologic subareas for purposes of characterizing groundwater quality and assimilative capacity, as listed in **Table G-10** and illustrated in Figure 2**,** and into four layers as listed in Table G-2. These subareas and layers are equivalent to those defined in the existing USGS groundwater model of the basins. The division of the basins into subareas/layers was performed to better understand the lateral and vertical distribution of S/Ns and help inform and prioritize potential implementation measures.

Areas seaward of the seawater intrusion barriers (referred to as coastal areas) have very high concentrations of TDS and chloride and lack groundwater production for potable use. S/N average concentrations and assimilative capacities of the Central Basin and West Coast Basin, both including and excluding the coastal areas are provided for comparison. The saline plume located inland of the WCBB[13] is shown in Figure 2. This is an area of high TDS and chloride associated with historical seawater intrusion prior to construction and operation of the WCBB. Average groundwater quality and available assimilative capacity were estimated for the West Coast Basin with the WCBB-inland saline plume area removed and without the coastal areas. This analysis without this saline plume was only performed for the current basin average water quality and assimilative capacity calculations. The saline plume could not be removed from the future water quality assessment because the baseline period calibration process and the future

[13] Inland saline plumes associated with the AGB and the DGB are much less extensive and therefore, not removed from the calculations for average groundwater quality.

groundwater quality predictions (described in Appendix I *Simulated Baseline and Future Salt and Nutrient Groundwater Quality)* rely on the water balances generated by the USGS groundwater flow model, which does not consider the WCBB-inland saline plume to be a subarea. The average groundwater quality in the coastal areas were also calculated to illustrate the very poor quality water (i.e. no assimilative capacity for TDS and chloride) in these areas and the impact of including these areas in the basin averages. S/N average concentrations and assimilative capacities were also calculated for the following subareas in the Central Basin: Montebello Forebay, Los Angeles Forebay, Whittier Area, Pressure Area including the coastal area, and Pressure Area excluding the coastal area. The USGS flow model subareas shown in Figure 2 look slightly different than the basin subareas presented in Figure 1 due to the gridded nature of the model domain and the inclusion of a small portion of Orange County near the AGB.

Table G-10 CBWCB Areas Assessed for Water Quality and Assimilative Capacity

Groundwater Basin	Subareas in the Central Basin
Central Basin (area seaward of AGB excluded)	Montebello Forebay
Central Basin (area seaward of AGB included)	Los Angeles Forebay
West Coast Basin (area seaward of DGB and WCBB excluded)	Whittier Area
West Coast Basin (area seaward of DGB and WCBB included)	Pressure Area (area seaward of AGB excluded)
West Coast Basin (area seaward of DGB & WCBB and WCBB-inland saline plume excluded) [a]	Pressure Area (area seaward of AGB included)
Coastal Areas (i.e. areas seaward of the AGB, DGB, and WCBB) [b]	

AGB – Alamitos Gap Seawater Intrusion Barrier
DGB – Dominguez Gap Seawater Intrusion Barrier
WCBB – West Coast Basin Seawater Intrusion Barrier

a – This basin area only used for current basin average and assimilative capacity calculations
b – Average groundwater quality and assimilative capacities for the coastal areas were calculated for both the West Coast Basin and Central Basin

It should be noted that two coastal areas in the West Coast Basin have been "de-designated" by the LARWQCB, which means these areas are no longer considered to have municipal beneficial uses due to degradation from historical seawater intrusion (LARWQCB, 1998 and 2011). Figure 3 shows the two de-designated areas; one is in the area underlying Terminal Island and portions of the Los Angeles and Long Beach Harbors and the second is in the El Segundo area. The groundwater in these areas is characterized by the LARWQCB as tidally-influenced in elevation and brackish to saline (LARWQCB, 2009). The de-designation of these coastal areas supports the conclusion that other coastal areas seaward of the barriers are impacted to the extent that groundwater production for potable use is unlikely in the foreseeable future.

3.5.2.2 Average S/N Groundwater Quality

In accordance with the SWRCB Recycled Water Policy, the average S/N concentrations of the basin or subbasin will be estimated using the most recent five years of available data, unless an alternate time period is approved by the local RWQCB. At the time the SNMP analysis was initiated[14], the last available sampling event for some wells occurred in 2011; thus, sampling results from wells during the most recent five years of data (January 2007 through mid-2012) were used to calculate current groundwater quality. The water quality data set for the Study Area is very extensive and includes semi-annual monitoring of the network of WRD nested wells and other data sets such as the SWRCB Division of Drinking Water (formerly CDPH) drinking water well database. Water quality from a small number of wells associated with environmental release sites were used to help establish Model Layer 1 water quality concentrations near the DGB and AGB, where nested and production well data were not available. **Table G-11** presents the quantity and type of wells used to estimate average groundwater quality in the Study Area.

The median TDS, chloride, and nitrate-N concentrations in wells in each model layer for the most recent 5-year water quality averaging period was plotted on maps. Figure 9 depicts different size and color circles representing median concentrations (dots maps). Wells were assigned to model layers based on the elevations of their screened intervals. Some wells (particularly production wells) are screened over multiple model layers and thus, were represented on more than one model layer map. For wells screened in multiple layers, water quality data from all layers screened were included in the averaging process. Wells with water quality but no well completion information were not included in the averaging analysis.

Medians were used instead of arithmetic averages because:

1. Well medians can be reliably calculated for datasets with mixed censored and non-censored data (i.e. detects and not detects), which was common in the nitrate dataset; and
2. Well medians allow for use of the entire water quality dataset while minimizing the skewing effect of potential data outliers and do not rely on parametric statistical methods that assume normal data distribution to remove potential outliers.

---

[14] The CBWCB SNMP data collection and analysis process began in May 2012.

MWs - monitoring wells WRD - Water Replenishment District of Southern California
TDS - total dissolved solids N - nitrogen # - Quantity
NA - not applicable; Model Layer 1 of limited extent or unsaturated in these areas (see Section 2.5.3 - USGS-Defined Aquifer System and Model Layers)"
Data from wells screened across multiple model layers are included in the analysis for all layers screened

Box plots were prepared to illustrate the distribution of the median well concentrations in each layer and subarea (Figure 33). Box plots illustrate the minimum, maximum, median, and 25th and 75th percentile concentrations for TDS, chloride, and nitrate-N in wells used to calculate the median concentration of each layer and subarea.

The TDS, chloride, and nitrate-N dots maps were then used to develop concentration contour maps for each layer and subarea using geographical information system (GIS) spatial analysis tools (Figure 10). Chloride concentration contour maps previously prepared by the LACDPW for each seawater instrusion barrier were also considered in developing the chloride concentration contours in the vicinity of the seawater barriers. The average TDS/chloride ratio of wells located in the vicinity of the barriers were used to incorporate the LACDPW chloride map information into the TDS concentration contour map prepared for the analysis. GIS spatial analysis tools were then used to extract the average concentrations for each subarea and layer.

In addition, the average water quality for all layers in each subarea was calculated by weighting the average concentration in each layer by the volume of water in each layer (in 2010). The volume of water in each subarea/layer was determined by calculating the volume of water in each model cell based on its size (2,640 feet x 2,640 feet), saturated thickness based on the 2010 groundwater surface elevation, and cell specific yield as assigned in the USGS/GBMP model. Cell volumes were then aggregated by subarea/layer. Finally, the water quality from all subareas and layers within each basin were amalgamated into a single average value for the Central Basin and West Coast Basin.

For each basin, two average concentrations were calculated: one average includes the coastal areas seaward of the seawater barriers and the other average excludes these coastal areas. For the West Coast Basin, a third average groundwater quality estimate was calculated excluding the WCBB-inland saline plume and coastal area (see Figure 17) in order to evaluate the impact of the plume on overall basin groundwater quality.

3.5.2.3 Available Existing Assimilative Capacity

The average TDS, chloride, and nitrate-N concentrations for each subarea/layer and for the Central Basin and West Coast Basin both with and without the coastal areas were compared to the BPO/BSBPO to determine the current existing available assimilative capacity. The available assimilative capacity is the difference between the average groundwater quality and the BPO or BSBPO.

3.5.3 TDS in Groundwater

3.5.3.1 TDS Concentrations

Figure 9 (dot maps) shows median TDS, chloride, and nitrate-N concentrations for monitoring wells and production wells in each model layer for the recent 5-year water quality averaging period (2007 through 2012). Note that Model Layer 1 does not exist across the entire Study Area and its extent is shown by gray shading in the figures in the top row of maps in Figure 9. As shown on Figure 24 and discussed in Section 2.5.3, Model Layer 1 extends into a very small portion of the Whittier Area where no water quality data exists. Similarly in the Los Angeles Forebay, Model Layer 1 is typically unsaturated and therefore, there are no monitoring well or production well data for this layer in this area. In some portions of the Central Basin Pressure Area and the West Coast Basin, Model Layer 1 also does not exist. Accordingly, for the SNMP analysis, loading was directed into Model Layer 2 in the areas where Model Layer 1 does not exist, as shown on the top row of maps in Figure 9. Not including Model Layer 1 in the Whittier Area and Los Angeles Forebay had almost no effect on the estimation of average groundwater quality because Model Layer 1 is very thin and contains a very small volume of water relative to the other model layers (2, 3, and 4). Circles of various sizes and colors representing the TDS medians are shown in the maps along the left column of the figure with Layer 1 on top and Layer 4 on the bottom.

In the Central Basin, TDS was detected above the BSBPO of 700 mg/L in some wells in all four layers; although the majority of wells are below the BSBPO. Elevated concentrations were detected in isolated wells in all of the subareas.

In the West Coast Basin, elevated TDS concentrations above the BSBPO of 800 mg/L were detected more frequently in Model Layers 2, 3, and 4 due to saline plumes caused by historical seawater intrusion. There were no nested monitoring wells or production wells screened in Model Layer 1 in the West Coast Basin. To address this data gap, TDS data from shallow monitoring wells (screened in Layer 1) associated with several environmental release sites were considered in the areas near the DGB and AGB.

Figure 33 shows the statistical distribution of the well medians as box plots for TDS, chloride, and nitrate-N for each subarea/layer. TDS box plots are shown along the left column of the figure with Layer 1 on the top and Layer 4 on the bottom. Box plots were prepared to illustrate the distribution of well median concentrations. The box plots illustrate the minimum, maximum, and 25th, 50th (median), and 75th percentile of well median concentrations in each subarea and model layer. Where only a dash is shown (i.e., no box plot), only one well median was available. Note that the West Coast Basin exhibits the widest distribution of TDS median concentrations, which is expected given that wells within and outside saline plumes represent a wide range of concentrations. Other areas show a narrower distribution of well median concentrations.

Figure 10 shows the TDS concentration contour maps along the left column of the figure. In order to further augment the contouring data set, annual depth-discrete chloride concentration contour maps previously prepared by LACDPW for each of the barriers were considered based on the observed relationship between chloride and TDS concentrations in wells located in the vicinity of the barriers.

As shown in Figure 10, there are a few hot spots of TDS concentrations above the BSBPO of 700 mg/L in the Central Basin, but the majority of the groundwater in the basin is below the BSBPO. In the West Coast Basin, large areas of elevated TDS concentrations above the BSBPO are observed near and inland of the seawater intrusion barriers and elsewhere as isolated hot spots.

3.5.3.2 Average TDS Concentrations and Assimilative Capacity

Based on the concentration contour maps (Figure 10), the average TDS concentrations were calculated in each subarea/layer. Volume-weighted concentrations for combined layers for each subarea, and for the Central Basin and West Coast Basin both with and without the coastal areas were calculated. In addition, averages were calculated for the West Coast Basin without the coastal areas and the WCBB-inland saline plume. The averages for just the coastal areas seaward of the barriers were calculated to illustrate the very poor quality water in these areas with respect to TDS and chloride and the impact of including these areas in the basin averages. **Table G-12** and Figure 11 present the average TDS concentrations, BSBPOs, and available assimilative capacity.

For the Central Basin, average TDS concentrations in all layers and the volume-weighted total average for the entire basin, both including and excluding the coastal area, are below the BSBPO of 700 mg/L. For the Central Basin, Model Layer 2 within the Los Angeles Forebay exceeds the TDS BSBPO; the average TDS concentration is weighted by the existence of only one well with a relatively high TDS concentration. Similarly, there is only one data point in the Whittier Area and as a result, Model Layers 3 and 4 and the overall subarea average exceed the TDS BSBPO. The distribution of higher TDS levels with depth in the Whittier Area indicates that the cause is likely naturally occurring conditions at depth, not a surface release. If a surface release were the source of the elevated TDS, one would expect higher TDS concentrations in the shallowest zones, which is not observed. Dissolution of formation materials high in silts and clays and/or of marine origin in the Whittier Area can result in naturally high TDS concentrations in ambient groundwater. The Puente Hills located north of the Whittier Area provide some of the source materials for the Whittier Area aquifers as well as for the Puente Subbasin located north of the Puente Hills. These source materials are relatively fine-grained and have resulted in high ambient TDS concentrations in the Puente Subbasin.

The Montebello Forebay, Central Basin Pressure Area (with and without the coastal area), and the entire Central Basin (with and without the coastal area), are all below the TDS BSBPO in all layers and in the overall average of all layers. The average TDS concentrations for the entire Central Basin both including and excluding the coastal area are below the BSBPO. There is 162 mg/L of available existing assimilative capacity for TDS in the Central Basin when the coastal area is included and 171 mg/L of available capacity when the coastal area is excluded.

For the West Coast Basin, average TDS concentrations in all layers and the volume-weighted total average for the entire basin, both including and excluding the coastal areas, exceed the BSBPO of 800 mg/L. With the coastal areas excluded, the average TDS concentration in Model Layer 3 is just below the BSBPO, while all other layers and the combined layers exceed the BSBPO. There is -624 mg/L of assimilative capacity in the West Coast Basin when the coastal areas are included and -90 mg/L of assimilative capacity when the coastal areas are excluded. The negative numbers indicate that there is no existing available assimilative capacity for TDS in the West Coast Basin as a result of historical seawater intrusion. Nonetheless, existing implementation measures including the seawater barriers and desalters are reducing overall TDS levels in the basin and additional proposed projects described in Appendix J *Implementation Plan,* including increased AWT recycled water recharge at the barriers and expanded desalter operations, will likely further reduce TDS levels in the future. When the coastal areas and the WCBB-inland saline plume are removed from the West Coast Basin average, there is 53 mg/L of available assimilative capacity for TDS, illustrating the significant impacts of saline plumes on the overall basin average.

Table G-12 Average TDS, Chloride, and Nitrate Concentrations in Subareas/Layers and in the Central Basin and West Coast Basin

TDS - total dissolved solids

Cl - chloride

NO_3-N - nitrate as nitrogen

NA - not applicable; no Model Layer 1 in these areas

Averages based on groundwater concentration contour maps; average of all layers is a weighted average based on area and aquifer thickness

Negative numbers indicate there is no available assimilative capacity

BPO/BSBPO - Basin Plan Objective or Basin Specific Basin Plan Objective

(orange shading) - Average concentration indicated exceeds BPO

(grey shading) - Model Layer 1 not included; typically unsaturated within the Los Angeles Forebay and of very limited extent Whittier Area (see explanation in Section 2.5.3)

a - Includes both Central Basin and West Coast Basin

b - Elevated TDS and chloride concentrations in the Whittier Area are likely naturally occurring as discussed in Section 3.5.3.2

For the coastal areas, average TDS concentrations in all layers and the volume-weighted total average for all layers exceed the BSBPOs of 700 mg/L and 800 mg/L in the Central Basin and West Coast Basin, respectively. There is -1,764 and -1,664 mg/L of assimilative capacity in the coastal areas in the Central Basin and West Coast Basin, respectively. The negative number indicates that there is no existing available assimilative capacity for TDS in the coastal areas as a result of seawater intrusion. The results for the coastal areas also illustrate the significant impact that the coastal areas have on overall basin averages. Based on the high TDS levels, groundwater production for potable use is unlikely to occur in the foreseeable future in the coastal areas.

3.5.1 Chloride in Groundwater

3.5.1.1 Chloride Concentrations

The middle column of plots on Figure 9 show median chloride concentrations (dots maps) for wells in each model layer, with Model Layer 1 on top and Model Layer 4 on the bottom.

In the Central Basin, chloride was detected below the BSBPO of 150 mg/L in most wells in all four layers. Elevated chloride concentrations were detected in one well near the coast in Model Layer 1, likely due to historical seawater intrusion.

In the West Coast Basin, elevated chloride concentrations above the 250 mg/L BSBPO are detected more frequently in Model Layers 2, 3, and 4, due to saline plumes. There are no nested monitoring wells or production wells screened in Model Layer 1 in the West Coast Basin. To address this data gap, chloride data from shallow monitoring wells (screened in Layer 1) associated with several environmental release sites with were considered in the areas near the DGB and AGB.

Figure 33 shows the statistical distribution of the chloride medians as box plots for each subarea/layer. Chloride box plots are shown in the middle column of charts, with Model Layer 1 on the top and Model Layer 4 on the bottom. Note that the West Coast Basin exhibits the widest distribution of chloride median concentrations, which is expected given that wells within and outside saline plumes are represented. Other areas show a smaller distribution of values.

Figure 10 shows the contoured chloride maps in the middle column of the figure. In order to further augment the contouring data set, annual depth-discrete chloride concentration contour maps previously prepared by LACDPW for each of the barriers were also considered. As shown in Figure 10, chloride concentrations in most of the Central Basin are below the BSBPO of 150 mg/L. In the West Coast Basin, large areas of elevated chloride concentrations are detected near and inland of the seawater intrusion barriers, as well as in isolated hot spots.

3.5.1.2 Average Chloride Concentrations and Assimilative Capacity

Based on the groundwater quality contour maps (Figure 10), the average chloride concentration in each model subarea/layer was calculated. The combined volume-weighted average concentration in all four layers was calculated for each subarea and for the Central Basin and West Coast Basin (both including and excluding the coastal areas). Table G-12 and

Figure 12 present the average chloride concentrations, the BSBPO, and available assimilative capacity.

For the Central Basin, average chloride concentrations in all layers and the volume-weighted total average for the entire basin, both including and excluding the coastal area, are below the BSBPO of 150 mg/L. Model Layer 4 in the Whittier Area exceeds the BSPO; although, the average of all layers in the Whittier Area is below the BSBPO. Similar to the results for TDS, elevated chloride at depth in the Whittier Area is likely due to naturally occurring conditions, not a surface release. If a surface release were the source of the elevated chloride, one would expect higher chloride concentrations in the shallowest zones, which is not observed. Dissolution of formation materials of marine origin in the Whittier Area can result in naturally high chloride concentrations in ambient groundwater. The adjacent Puente Hills are comprised of a thick sequence of sedimentary marine bedrock units. These marine source rocks for the aquifers in the Whittier Area are fine-grained and a potential source of the elevated chloride observed at depth. The amalgamated Central Basin layer averages, both including and excluding the coastal area, are also below the BSBPO. There is 77 mg/L of available assimilative capacity in the Central Basin when the coastal area is included and 83 mg/L of available assimilative capacity when the coastal area is excluded.

For the West Coast Basin, average chloride concentrations in all layers and the volume-weighted total average for the entire basin, both including and excluding the coastal areas, exceed the BSBPO of 250 mg/L. There is -410 mg/L of assimilative capacity in the West Coast Basin when the coastal area is included and -56 mg/L of assimilative capacity when the coastal areas are excluded. The negative numbers indicate that there is no existing available assimilative capacity for chloride in the West Coast Basin due to seawater intrusion. Nonetheless, existing implementation measures including the seawater barriers and desalters are reducing overall chloride levels in the basin and additional proposed projects described in Appendix J *Implementation Plan,* including increased AWT recycled water recharge at the barriers and expanded desalter operations, will likely further reduce chloride levels in the future. When the coastal areas and the WCBB-inland saline plume are removed from the West Coast Basin average, there is 26 mg/L of available assimilative capacity for chloride, illustrating the significant impacts of saline plumes on the overall basin average.

For the coastal areas, average chloride concentrations in all layers and the volume-weighted total average for all layers exceed the BSBPOs of 150 mg/L and 250 mg/L in the Central Basin and West Coast Basin, respectively. There is -1,193 and -1,093 mg/L of assimilative capacity in the coastal areas in the Central Basin and West Coast Basin, respectively. The negative numbers indicate that there is no existing available assimilative capacity for chloride in the coastal areas as a result of seawater intrusion. The results for the coastal areas also illustrate the significant impact that the coastal areas have on overall basin averages. Based on the high chloride levels, groundwater production for potable use is unlikely to occur in the foreseeable future in the coastal areas.

3.5.2 Nitrate in Groundwater

3.5.2.1 Nitrate-N Concentrations

The right column of maps on Figure 9 shows median nitrate-N concentrations for wells in each model layer, with Model Layer 1 on top and Model Layer 4 on the bottom.

In the Central Basin, nitrate-N is below the MCL/BPO of 10 mg/L in most wells in all four layers, with a few exceptions. A few wells with higher nitrate-N concentrations but below the MCL were observed in the Montebello Forebay (Model Layers 1, 2, and 3), Los Angeles Forebay (Model Layers 2 and 3), and Whittier Area (Model Layer 2). Two wells with elevated concentrations above the MCL were observed in the Central Basin Pressure Area (Model Layer 3) and in the Los Angeles Forebay (Model Layer 3).

In the West Coast Basin, a few wells with elevated nitrate-N concentrations but below the 10 mg/L MCL were observed in Model Layers 2 and 3; only two of the wells (in Layer 2) have median concentrations that exceed the MCL.

Figure 33 shows the statistical distribution of the nitrate-N median concentrations as box plots in each subarea/layer. Nitrate-N box plots are shown along the right column in the figure, with Model Layer 1 on the top and Model Layer 4 on the bottom. While there are a few wells containing nitrate-N above the MCL of 10 mg/L, the box plots show the majority of wells have low nitrate-N median concentrations significantly below the MCL.

Figure 10 shows the nitrate-N concentration contour maps along the right column in the figure. As shown in the figure, only isolated hot spots of elevated nitrate-N concentrations are detected in Model Layers 1, 2, and 3 in both the Central Basin and West Coast Basin.

3.5.2.2 Average Nitrate-N Water Quality and Assimilative Capacity

Based on the groundwater quality contour maps (Figure 10), the average nitrate-N concentration in each subarea/layer was calculated. The combined volume-weighted average concentration in all four layers was calculated for each subarea and for the Central Basin and West Coast Basin (both including and excluding the coastal areas). Table G-12 and Figure 13 present the average nitrate-N concentrations, the MCL/BPO of 10 mg/L, and available assimilative capacity. Overall, nitrate-N concentrations in the CBWCB are significantly below the MCL/BPO and thus, nitrate is not considered a constituent of concern in the CBWCB and there is available assimilative capacity in both basins.

In the Central Basin, average nitrate-N concentrations in all subareas/layers are significantly below the MCL of 10 mg/L. The amalgamated average nitrate-N concentrations in the Central Basin, both including and excluding the coastal area, are also below the MCL. There is 9.72 mg/L of available assimilative capacity in the Central Basin whether the coastal area is excluded or included.

For the West Coast Basin, average nitrate-N concentrations in all layers and the volume-weighted total average for the entire basin, both including and excluding the coastal areas, are significantly below the MCL of 10 mg/L. There is 9.96 mg/L of available assimilative capacity in the West Coast Basin when the coastal areas are included and 9.95 mg/L of available assimilative capacity when the coastal areas are excluded.

Attachment G-A

Construction Information for WRD Nested Groundwater Monitoring Wells

Below is a table summarizing the construction information for over 300 nested groundwater monitoring wells at more than 55 locations in the Central Basin and West Coast Basin. These wells are owned by the Water Replenishment District of Southern California (WRD) and sampled semi-annually as part of WRD's Regional Groundwater Monitoring Program (RGWMP). Each nested well is screened in a specific aquifer, which helps to monitor regional groundwater quality and water levels. These nested monitoring wells are depicted in Figure 25.

List of Figures

List of Figures

1 Introduction

This Appendix H describes the baseline and future water balances in the Central Basin and West Coast Basin (CBWCB). Key components of this appendix include:

- A description of CBWCB annual water balances for the baseline period from Water Year (WY) 2000-01 to 2009-10,
- Based on goals and objectives for projects and water use, a prediction of CBWCB annual water balances for the future planning period from WY 2010-11 to 2025-25, and
- Estimation of changes in groundwater levels due to implementation of projects in the future planning period.

Section 2 describes the baseline and future planning period water balances in the CBWCB. All sources of inflow and outflow from the basins are described. Future planning period changes in inflows and outflows are based on various planning documents, goals and objectives for recycled water use and stormwater capture, and input from the CBWCB stakeholders. Section 3 describes changes in groundwater levels due to implementation of proposed projects in the future planning period. References cited in this appendix are provided at the end of the Salt and Nutrient Management Plan (SNMP).

2 Baseline and Future Planning Period Water Balance

2.1 Baseline Period Data Sources

In order to estimate the baseline period salt and nutrient (S/N) balance in the CBWCB, it is necessary to have an understanding of the baseline period groundwater inflows and outflows (i.e., the water balances). The baseline period covers WY 2000-01 to 2009-10, as established in the LARWQCB-approved *SNMP Workplan* (CBWCB Stakeholders, 2011). The water balance changes from year to year based on a number of factors, including replenishment activities, precipitation, availability of imported water supplies, subsurface inflow and outflow (e.g., groundwater flow directions and gradients), and groundwater extraction. The difference between the basin inflow and outflow is the change in groundwater storage in the basin.

The water balance consists of estimates of specific inflows and outflows for each basin. The various groundwater inflows and outflows are reported by the Water Replenishment District of Southern California (WRD) in their annual *Engineering Survey and Report* (accessed at: http://www.wrd.org/engineering/groundwater-engineering-reports.php), by the Central Basin and West Coast Basin Watermaster[1] in their annual *Watermaster Service* reports for each basin

[1] As a result of the Judgment issued on December 18, 2013, the California Department of Water Resources is no longer Watermaster of the Central Basin. Beginning July 1, 2014, the Watermaster is now comprised of three entities: 1) Administrative Body, 2) Water Rights Panel, and 3) Storage Panel. The Water Replenishment District of Southern California has been designated as the Administrative Body and will be responsible for preparing the annual *Watermaster Service* reports and submitting them to the Water Rights Panel. The Water Rights Panel is

(accessed at: http://www.water.ca.gov/watermaster/aboutwatermaster/index.cfm). Imported water deliveries and groundwater pumping volumes are also provided in the *Watermaster Service* reports. Volumes of replenishment (managed aquifer recharge) water, groundwater pumping, and imported water and recycled water use are provided in WRD's annual *Engineering Survey and Reports*.

A calibrated groundwater flow model previously developed for the Study Area by the United States Geological Survey (USGS) was recently updated as part of the Groundwater Basins Master Plan (GBMP) (USGS, 2003; CH2MHILL, 2012b). Water balances developed as part of these groundwater modeling efforts were relied upon for some components of the SNMP water balances. Additionally, the USGS/GBMP modeling reports provided estimates of percolation of precipitation including irrigation return flows and other minor sources, mountain front recharge, and subsurface groundwater flow (USGS, 2003; CH2MHILL, 2012b).

2.2 Future Planning Period Data Sources

In conformance with the SWRCB Recycled Water Policy, estimated (known and/or predicted) potable and non-potable water recycling and stormwater recharge/use goals and objectives were developed as part of the SNMP. Projections were also provided for other components of the future planning period water balances.

The SNMP *Workplan* approved by the LARWQCB (Stakeholders, 2011) established a 10-year future planning horizon of WY 2010-11 to 2019-20. The CBWCB stakeholders agreed to extend the future planning ending date from WY 2019-20 to 2024-25 based on a suggestion by LARWQCB staff at the July 26, 2012 SNMP Stakeholder meeting. As a result, the future planning period was extended to 15 years, so from WY 2010-11 to 2024-25.

The characterization of future water balance components was facilitated by several ongoing planning efforts in the region. The 2012 update to the 2006 Greater Los Angeles County (GLAC) Integrated Regional Water Management Plan (IRWMP) (RMC, 2012b) provided information regarding water supply target volumes, which were obtained from regional planning documents and stakeholder review/input from the same agencies participating as stakeholders for the SNMP. Information was also obtained from the July 2012 Draft GBMP (CH2MHILL, 2012b), permits and planning documents for groundwater recharge projects, and other planning documents. Target volumes and objectives developed for the SNMP were coordinated with work being conducted as part of the Los Angeles Gateway Region IRWMP.[2] Preliminary water balance component goals and objectives developed for the SNMP were reviewed and refined with information provided by the CBWCB stakeholders.

One of the key goals of the GLAC IRWMP is to optimize local water supplies to reduce reliance on imported water. The 2012 update refined the target volumes established in the 2006 GLAC IRWMP. The GLAC IRWMP Region includes the CBWCB and consists of over 10 million

---

ultimately responsible for submitting the final *Watermaster Service* reports to the Superior Court of the State of California for filing.

[2] The Los Angeles Gateway Region includes 26 mainland cities and small portions of unincorporated areas in Southeastern Los Angeles County, a subset of the Central Basin. See http://www.gatewayirwmp.org/.

residents, portions of 4 counties, 92 cities, and hundreds of agencies and districts. To manage stakeholder outreach and data input, the GLAC IRWMP Region is divided into five subregions: 1) the South Bay Watershed; 2) the North Santa Monica Bay Watersheds; 3) the Lower San Gabriel River and Lower Los Angeles River Watersheds; 4) the Upper Los Angeles River Watersheds; and 5) the Upper San Gabriel River and Rio Hondo Watersheds (Figure 34). Two of the subregions essentially conform to the SNMP Study Area: 1) the Lower San Gabriel River and Lower Los Angeles River Subregion is comprised of the Central Basin and portions of abutting hills and 2) the South Bay Subregion is comprised of the West Coast Basin, Santa Monica Basin, Hollywood Basin, and portions of abutting hills. Information for the South Bay Subregion that is directly related to only the West Coast Basin was extracted to estimate future water balances for the SNMP.

Initial target volumes in the 2012 GLAC IRWMP were established using representative 2010 Urban Water Management Plans (UWMPs) from each subregion, groundwater adjudication documents, annual *Watermaster Service* reports, and recycled water master plans. The target volumes were refined through input from meetings of each Subregional Steering Committee and subsequently with input from a working group made up of water suppliers from each subregion. While the planning horizon for the 2012 GLAC IRWMP update is 2035, information was extracted or estimated to conform to the 2025 SNMP future planning horizon.

Development of the Draft GBMP was initiated by WRD to provide the CBWCB stakeholders with a roadmap for collaborative and strategic development of potential future projects and programs that will more effectively use groundwater in the basins to increase water supply reliability. Increased reliability is based on two scenarios: 1) pumping the maximum amount of the adjudicated water rights each year (the Allowable Pumping Allocation), and 2) pumping groundwater beyond adjudicated rights. Based on a long-term planning horizon, the Draft GBMP identified a range of projects to ensure that additional replenishment water will be supplied to meet pumping rights and to reduce reliance on imported water. Because the GBMP planning horizon is beyond 2025 and many of the potential projects are uncertain and conceptual, some of the projects identified in the Draft GBMP were not used to develop the SNMP water budget targets.

For the SNMP target volumes, additional information that was considered include existing LARWQCB permits, environmental documents, and information/input from the CBWCB stakeholders. It is important to acknowledge that work on the 2012 GLAC IRWMP and finalization of target volumes will continue beyond the completion of the SNMP and thus, there may be some difference in the final target volumes referenced in the GLAC IRWMP and SNMP. Some future planning period water balance components identified in the SNMP are not expected to change significantly and are projected to remain at the baseline period average throughout the future planning period.

2.4 Groundwater Recharge (Inflows)

Major sources of groundwater inflows to the CBWCB include:

- Managed aquifer recharge in spreading grounds, instream facilities, and at the seawater intrusion barriers;
- Deep percolation of precipitation;
- Irrigation return flows;
- Percolation of runoff from surrounding uplands (mountain front recharge); and
- Subsurface groundwater inflow from adjacent groundwater basins.

Other minor potential sources of groundwater recharge include leaking pipes, septic systems, and stream losses (not associated with managed aquifer recharge). In the CBWCB, losses from leaking pipes and septic systems are believed to be small in comparison to the major sources. Natural stream recharge (other than the managed aquifer recharge in the San Gabriel River in the Montebello Forebay) is also limited, as most major rivers and streams are concrete lined.

The largest volume of recharge in the Central Basin occurs in the Montebello Forebay via the spreading grounds and instream facilities (i.e., check dams) in the San Gabriel River. Other major sources of recharge include injection at the Alamitos Gap Seawater Intrusion Barrier (AGB), subsurface groundwater inflow, deep percolation of precipitation, irrigation return flows, and mountain front recharge. Additionally, the City of Long Beach has four aquifer storage and recovery (ASR) wells that can be used to inject imported water available in wet years into the Central Basin and have the capacity to extract water when needed. For the SNMP future planning period, the City of Long Beach only plans to use the wells for extraction[3].

In the West Coast Basin, aquifers are generally confined and natural replenishment is dominated by subsurface inflows (CH2MHILL, 2012b). Sources of recharge in the West Coast Basin includes injection at the seawater intrusion barriers including the West Coast Basin Seawater Intrusion Barrier (WCBB) and Dominguez Gap Seawater Intrusion Barrier (DGB), subsurface groundwater inflow, deep percolation of precipitation, mountain front recharge, irrigation return flows, and the Dominguez Gap Spreading Grounds (DGSG).

2.4.1 Spreading Grounds and Instream Recharge

Managed aquifer recharge (MAR) in the CBWCB occurs through:

1) Three spreading grounds – Includes the Rio Hondo Spreading Grounds (RHSG) and San Gabriel River Spreading Grounds (SGRSG) in the Montebello Forebay and the DGSG near the southern border between the Central Basin and West Coast Basin; and
2) Multiple instream recharge facilities – Includes instream check dam facilities along the San Gabriel River in the Montebello Forebay.

[3] Personal communication from Ted Johnson, WRD, August 6, 2012.

These groundwater replenishment activities directly recharge Model Layer 1 (shallowest layer) with subsequent movement to lower model layers and other subareas.

2.4.1.1 Montebello Forebay Spreading Grounds and Instream Recharge

The MFSG, consisting of both the RHSG and SGRSG and located downstream of the Whittier Narrows Dam, recharge a significant amount of water in the Montebello Forebay (Figure 1). The MFSG are owned, operated, and maintained by the Los Angeles County Department of Public Works (LACDPW). The RHSG consist of spreading basins on both the east and west sides of the Rio Hondo. The recharge basins of the SGRSG are located on the west side of the San Gabriel River. Instream infiltration along the unlined stretch of the San Gabriel River in the Montebello Forebay is enhanced by the presence of inflatable rubber dams (Figure 4). These dams can be inflated to restrict flow in the unlined channel to promote recharge within the Montebello Forebay.

Currently, water delivered to the MFSG includes a mix of tertiary-treated recycled water, imported water, and local stormwater. Managed aquifer recharge in the Montebello Forebay was first implemented in WY 1937-38 and the first full year of recharge with recycled water began in WY 1962-63. The recycled water is produced by the San Jose Creek, Whittier Narrows, and Pomona Water Reclamation Plants (WRPs), which are owned and operated by the Sanitation Districts of Los Angeles County (SDLAC). Untreated imported water from the Colorado River (CR) and State Water Project (SWP) is provided by the Metropolitan District of Southern California (MWD). Local water and stormwater recharged in the Montebello Forebay includes natural runoff and controlled releases from upstream dams. In addition, a small amount of groundwater imported from the San Gabriel Basin was historically recharged at the MFSG. WRD purchases the recycled water and imported water recharged in the Montebello Forebay.

The volumes and sources of water recharged in the Montebello Forebay between WY 2000-01 and 2009-10, the SNMP baseline period, are shown in **Table H-1**. Data from the SNMP baseline period was used for assessment of water balances and S/N balances, and provide the basis for calibration to observed groundwater quality trends discussed in Appendix I *Simulated Baseline and Future Salt and Nutrient Groundwater Quality*. The average annual amount of water recharged in the Montebello Forebay during the baseline period was about 118,000 acre-feet per year (AFY).

During the future planning period, a recycled water project under WRD’s Groundwater Reliability Improvement Program (GRIP) is expected to be implemented to supply advanced treated and/or increased tertiary-treated recycled water recharge at the MFSG to completely replace imported water (up to 21,000 AFY). Two project alternatives, GRIP Recycled Water Project A (GRIP A) and GRIP Recycled Water Project B (GRIP B), are being considered for implementation. For GRIP A, up to 11,000 AFY of additional tertiary-treated recycled water from the San Jose Creek WRP and up to an additional 10,000 AFY of advanced treated recycled water will be recharged in the Montebello Forebay to replace imported water. For GRIP B, up to 21,000 AFY of additional tertiary-treated recycled water from the San Jose Creek WRP will be recharged in the Montebello Forebay to replace imported water. Both proposed project

All values in acre-feet per year
USEPA - United States Environmental Protection Agency
WRP - Water Reclamation Plant
WRD - Water Replenishment District of Southern California
MWD - Metropolitan Water District of Southern California
SWP - State Water Project
CR - Colorado River
AF - acre-feet

a - Data from: WRD, March 4, 2011, Engineering Survey and Report
b - Relative volume of water from SWP and CR provided by Kathy Kunysz of MWD, numbers are best approximation
c - Imported and recycled water from the Whittier and San Jose Creek WRPs are purchased; local water and Pomona WRP efffleunt are incidental recharge; purchased water may have losses to San Gabriel Basin before reaching the Montebello Forebay Spreading Grounds
d - USEPA extracted groundwater from Whittier Narrows, considered imported water
e - USEPA extracted groundwater from the Whittier Narrows, considered imported water
f - Includes 13,000 AF of water banked by Long Beach under a storage agreement with WRD (792 AF in Feb 2003 and 12,210 AF in March 2004)
g - CBMWD purchased 1,510 AF imported water for spreading for Cities of Downey, Lakewood, and Cerritos
h - Includes the Rio Hondo Spreading Grounds, Whittier Narrows Conservation Pool, San Gabriel River Spreading Grounds and unlined portion of the San Gabriel River

alternatives have the same total recharge volumes; however, GRIP B is projected to start in WY 2014-15, while GRIP A would not start until WY 2017-18 and the water quality of the recharge water would be different under the different scenarios.

The GRIP A and GRIP B alternatives are the end result of a long process of analysis of many different alternatives including consideration of different levels of recycled water treatment and blending, different wastewater treatment facilities providing the recycled water, continued imported water deliveries, alternative imported water supplies, desalination, and increased stormwater capture (MWH, 2009a through 2009l; RMC, 2011b; SDLAC, 2012; and CH2MHILL, 2012c). At this time, GRIP A and GRIP B are being further evaluated by WRD in terms of feasibility and cost and a Draft Environmental Impact Report was issued for public review in March 2014 (accessed at: http://www.wrd.org/business/water-replenishment-grip.php). In the Draft EIR, GRIP A was identified as the "proposed project," while GRIP B was identified as an "alternative" to the "proposed project" (AECOM, 2014). As a result, it is anticipated that GRIP A likely would be the project to be implemented by WRD. However, this is subject to change until the Final EIR is prepared and certified by WRD.

Table H-2 presents the sources of water and target volumes for MAR in the Montebello Forebay from WY 2010-11 through 2024-25 (SNMP future planning period) based on implementation of GRIP B. **Table H-3** presents the sources of water and target volumes for MAR in the Montebello Forebay from WY 2010-11 through 2024-25 (SNMP future planning period) based on implementation of GRIP A. While the sources of recharge water are different, the total volume of water recharged is the same for both alternatives. As indicated in Tables H-2 and H-3, the total volume of water recharged in the Montebello Forebay is projected to increase slightly from the baseline period average of about 118,000 AFY to about 125,000 AFY by WY 2024-25 due to improvements in stormwater capture and increased use of recycled water, which is a more reliable supply compared to imported water.

The Draft GBMP discusses the potential to fully utilize SDLAC's San Jose Creek WRP and Los Coyotes WRP with the possibility to provide up to an additional 66,800 AFY of recycled water for spreading and injection in the Montebello Forebay (including the proposed GRIP Recycled Water Project). With the exception of the proposed GRIP Recycled Water Project, these future projects were projected to occur beyond the SNMP 2025 planning horizon and therefore, were not discussed in the SNMP.

Several projects, presented below, were identified by LACDPW that also provide additional flexibility for MFSG recharge operations, but will not specifically expand recycled water or imported water recharge and thus do not affect recharge target volumes[4].

- Rio Hondo Spreading Grounds Basin 6E to 8E Connection – The connection will allow for increased flexibility to capture 1,200 AFY of recycled water.
- San Gabriel River Levee Repair – The loss of the levee could temporarily suspend all recharge activities at the San Gabriel River Spreading Grounds and San Gabriel River.

---

b - Relative volume of water from SWP and CR for baseline provided by Kathy Kunysz of MWD; numbers are best approximation; relative volume of SWP and CR water for future planning period based on baseline distribution

c - Imported and recycled water from the Whittier Narrows and San Jose Creek WRPs are purchased; local water and Pomona WRP effluent are incidental recharge; purchased water may have losses to San Gabriel Basin before reaching the Spreading Grounds; distribution between plants for future planning period based on baseline averages; after 2014, additional increased flow is from SJCWRP; local water capture for future planning period is based on 30-year average using data from WRD Annual Engineering Survey and Reports

d - WRR (Order No. 91-100), which was amended in April 2009 via Order No. R4-2009-048, allows the maximum quantity of recycled water spread to be 35 percent based on the combined total inflow (imported water, stormwater, precipitation, and underflow) during a period of five years; LARWQCB (2013) approved increase in compliance averaging period to ten years due to below normal rainfall for seven of the last ten years

e - The projected increase reflects the ability to increase the recycled water replenishment as a result of using the five-year averaging period and thus counting larger stormwater inputs

f - This increase reflects the start of GRIP A (10,000 AFY of advance treated recycled water)

g - Includes the Rio Hondo Spreading Grounds, Whittier Narrows Conservation Pool, San Gabriel River Spreading Grounds and unlined portion of San Gabriel River

h - This is the increase or decrease between the baseline period average and WY 2025

- San Gabriel River Recycled Water Outlet – The addition of another outlet to the San Gabriel River from the recycled water pipeline delivering water from the San Jose Creek WRP will allow for increased flexibility of spreading 400 AFY of recycled water.
- Peck Road Spreading Basin Pump Station and Pipeline – The pump station would be located at Peck Road Spreading Basin, which could spread water to the San Gabriel River or direct flows to the Rio Hondo Concrete Channel. This project would reduce the loss of imported water (and stormwater) due to evaporation and percolation at Peck Road.

Local water recharged in the Montebello Forebay includes stormwater and river base flow. There are no additional stormwater conservation projects that will be constructed by the 2025 SNMP planning horizon to add stormwater conservation capacity to the forebay. Based on WRD's recommendation, the 30-year average local water volume[5] was used to calculate the projected volumes beginning in WY 2010-11, as shown in Tables H-2 and H-3.

There are no significant future Montebello Forebay-specific projects that will increase stormwater recharge within the SNMP 2025 planning horizon; however, a number of projects have been recently constructed that enhance stormwater replenishment and are included as part of the baseline conditions:

- Spreading Grounds Interconnection Pipeline – Increases stormwater capture by about 1,300 AFY (CH2MHILL, 2012b);
- New San Gabriel River Rubber Dams – Increases stormwater capture and recharge by about 3,600 AFY (Johnson, 2011; CH2MHILL, 2012b); and
- Whittier Narrows Dam Conservation Pool Project – Operational enhancements to increase the conservation pool elevation behind the dam from 195 to 205 feet above mean sea level (ft-msl) (WRD, 2011; CH2MHILL, 2012b). The project is being implemented in phases. Beginning in 2004, the conservation pool was raised to 201.6 ft-msl, which resulted in an estimated additional capture and recharge of 3,000 AFY of stormwater (WRD, 2011).

Several projects were identified, listed below, that will provide future stormwater replenishment for the Montebello Forebay, but will be constructed beyond the SNMP 2025 planning horizon.

- The next phase of the Whittier Narrows Dam Conservation Pool Project will increase the conservation pool elevation behind the dam from 201.6 to 205 ft-msl resulting in an estimated additional capture of 1,100 AFY of stormwater.

The Montebello Forebay Increased Extraction and Intrabasin Transfer Project was described in the Draft GBMP. This potential project is proposed to provide for 25,000 AFY of groundwater extraction to reduce groundwater levels and a pipeline will be constructed to deliver water to participating pumpers as far south as Long Beach, which will allow for 17,000 AFY of additional stormwater recharge at the MFSG, if implemented.

---

[5] Personal communication, Ted Johnson, WRD, August 22, 2012.

2.4.1.2 Dominguez Gap Spreading Grounds

The DGSG, located along the Los Angeles River near the southern boundary between the Central Basin and West Coast Basin (Figure 1), are owned, operated, and maintained by the LACDPW. Originally, the spreading grounds included basins on both the east and west sides of the river; the east side basins recharged the Central Basin and the west side basins recharged the West Coast Basin. In 2007, construction began for the DeForest Treatment Wetlands Project, jointly sponsored by LACDPW and the City of Long Beach. This project converted the east basins into wetlands, which provide habitat and surface water quality improvement, while essentially eliminating groundwater recharge. Thus, only the west basins remain and continue to operate as managed recharge facilities.

The source of recharge water at the DGSG is controlled flows from the Los Angeles River low-flow channel and uncontrolled flows from storm drains. The DGSG directly recharge Model Layer 1 with subsequent movement to lower model layers in the West Coast Basin. **Table H-4** shows recharge volumes during the 10-year baseline period and projected volumes for the future planning period. It is assumed that historically 50% of the recharge water went to the east basins (Central Basin) and 50% went to the west basins (West Coast Basin) through 2007. After 2007, all recharge is allocated to the West Coast Basin. Historical conservation volumes for WY 2000-01 through 2009-10 were obtained from the LACDPW.

The proposed DGSG West Basin Percolation Enhancement Project will install vertical trenches/drains through poorly draining strata underlying the bottom of the DGSG's west basins to increase their percolation capacity. It is expected that this project will allow for an additional 1,000 AFY of stormwater to replenish the West Coast Basin by WY 2017-18[6]. For WY 2010-11 through 2016-17, the 10-year baseline period average (WY 2000-01 through 2009-10) was used to estimate projected stormwater capture volumes. The average annual amount of water recharged at the DGSG during the baseline period was about 760 AFY.

2.4.2 Seawater Intrusion Barriers

There are three seawater intrusion barriers currently operating in the Study Area, including the WCBB and DGB in the West Coast Basin and the AGB located in the Central Basin and adjacent Orange County Basin. The barriers receive recycled water that has undergone advanced water treatment (AWT) from different treatment facilities and imported water that is a blend of treated water from the CR and SWP supplied by the MWD's Jensen and Diemer Water Treatment Plants (WTP). The source water at the Jensen WTP is only from the SWP. The source water at the Diemer WTP is from both the CR and SWP. The blend of water from the CR and SWP varies considerably from year to year.

Based on USGS' groundwater model, all water injected at the seawater barriers (in the Central Basin and West Coast Basin) recharges the basins, or at a minimum up to 20% of the injected water stays seaward of the barriers at any one time as a freshwater buffer that would quickly decay if the barriers were shut down (USGS, 2003).

---

AFY – acre-feet per year DGSG – Dominguez Gap Spreading Grounds

a - Historical conservation volumes for water years 2000-01 through 2009-10 were obtained from the LACDPW

b - Reflects annual 10-year average

c - Reflects the startup of the DGSG West Basin Percolation Enhancement Project

AWT recycled water will replace imported water at all three barrier locations during the SNMP future planning period, and overall injection volumes are projected to increase.

2.4.2.1 Alamitos Gap Seawater Intrusion Barrier

The AGB is located at the southern end of the Central Basin, specifically at the Los Angeles-Orange County border about two miles inland from the mouth of the San Gabriel River (Figure 2). In 1964, LACDPW and Orange County Water District (OCWD) constructed the AGB, partially in Orange County and partially in Los Angeles County. The AGB is jointly owned and maintained by the LACDPW and OCWD and operated under the direction of the AGB Joint Management Committee. WRD purchases the water for injection into the Los Angeles County side of the AGB and the OCWD purchases the water injected into the Orange County side of the AGB. Historically, the AGB received treated imported water from MWD's Jensen and Diemer WTPs. Since October 2005, AWT recycled water, produced by WRD's Leo J. Vander Lans Advanced Water Treatment Facility (Vander Lans AWTF), also has been delivered to the AGB for injection. The Vander Lans AWTF is owned by WRD and operated and maintained by the Long Beach Water Department. The source water for the Vander Lans AWTF is tertiary-treated recycled water from the SDLAC Long Beach WRP.

There are currently 43 injection wells used to provide a freshwater pressure ridge that breaks the landward gradient of intruding seawater. Most of the injection at the AGB occurs in Model Layers 2 and 3 with a small amount in the lower portion of Model Layer 1. The baseline period and future projected volumes and sources of water injected at the AGB, WCBB and DGB are provided in **Table H-5**. During the SNMP baseline period, an average of about 5,200 AFY was injected/recharged at the AGB.

AWT recycled water is projected to fully replace imported water at the AGB in WY 2014-15, since the Vander Lans AWTF was expanded at the end of 2014 to produce from 3,360 AFY to 8,960 AFY of AWT recycled water. However, minor volumes of treated imported water, supplied by MWD, may be utilized as necessary through the future due to temporary operational and maintenance issues that may be encountered at the Vander Lans AWTF or at the AGB. Table H-5 presents the recycled water and imported water target volumes for the AGB from 2010 through 2025. AWT recycled water is expected to fully replace imported water, with flow projected to increase to 7,200 AFY beginning WY 2014-15 and overall injection is expected to be approximately 2,000 AFY higher by WY 2024-25 compared with the baseline period average.

2.4.2.2 West Coast Basin Seawater Intrusion Barrier

The WCBB was expanded from the original experimental project in Manhattan Beach in 1953. It now consists of a line of 153 injection wells along the coastline extending from Los Angeles International Airport to the Palos Verdes Hills (Figure 2). The WCBB is owned, operated, and maintained by the LACDPW. Historically, treated imported water (from the SWP and CR) supplied by MWD's Jensen and Diemer WTPs, along with AWT recycled water from West Basin Municipal Water District's (WBMWD's) Edward C. Little Water Recycling Facility (Edward C. Little WRF)was injected at the WCBB. The source water to the Edward C. Little WRF is

SWP - Treated water from State Water Project supplied by MWD's Diemer or Jensen WTP
CR - Treated water from Colorado River supplied by MWD's Diemer WTP
WRD - Water Replenishment District of Southern California
MWD - Metropolitan Water District of Southern California
AWT - Advanced water treatment
WTP - Water Treatment Plant
WBMWD - West Basin Municipal Water District
LADWP - City of Los Angeles Department of Water and Power

a - Data for baseline period from: WRD, March 4, 2011, Engineering Survey and Report; Alamitos Gap Barrier and Dominguez Gap Barrier AWT recycled water average is from 2005-06 to 2009-10

b - Relative volume of water from SWP and CR for baseline period provided by Kathy Kunysz of MWD; numbers are best approximation; relative volume of water from SWP and CR for future planning period are average of baseline period distribution

c - Advanced treated recycled water supplied by City of Los Angeles Terminal Island Water Reclamation Plant/Advanced Water Treatment Facilities

d - Advanced treated recycled water supplied by WRD's Leo J. Vander Lans Advanced Water Treatment Facility

e - Advanced treated recycled water supplied by WBMWD's Edward C. Little Water Recycling Facility

f - Treatment plant not in operation due to maintenance from October 2011 to November 2012

g - Information provided by Ted Johnson, WRD, August 17, 2012; Uzi Daniel, WBMWD, August 6, 2012; and Seung Tag Oh, LADWP, August 15, 2013

h - Reflects the start date for the project expansion; AOP is applied to the full flow; under Waste Discharge and Water Recycling Requirements (WDR and WRR) Order No. R4-2005-0061, the current permit allows up to 3,360 AFY of recycled water to be used for the barrier; the permit will be amended for the expansion

i - Reflects implementation of the Phase V recycled water project expansion; under WDR (Order No. R4-2006-0009), WBMWD is allowed to use up to 14,000 AFY of advanced treated recycled water, and ultimately 19,600 AFY of advanced treated recycled water

j - Reflects the start date for the project expansion; under WRR (Order No. R4-2003-0134), LADWP is allowed to use up to 5,600 AFY of advanced treated recycled water; the permit will be amended for the expansion

k - This is the increase or decrease in recycled water and imported water use between the average baseline period and water year 2024/25 secondary effluent from the City of Los Angeles Hyperion WRP. AWT recycled water injection began in 1995 at the WCBB.

WRD purchases all the water injected into the WCBB. Most of the water injection at the WCBB occurs in Model Layers 3 and 4 with a smaller amount in Model Layer 2. The baseline period and future planning period volumes and sources of water injected at the WCBB are provided in Table H-5. During the baseline period, an average of about 15,000 AFY was injected/recharged at the WCBB.

In WY 2013-14, the Edward C. Little WRF was expanded to produce from 14,000 AFY to 19,600 AFY of AWT recycled water. It is anticipated that AWT recycled water will fully replace imported water for injection at the WCBB beginning in WY 2013-14. However, minor volumes of treated imported water, supplied by MWD, may be utilized as necessary for injection through the future due to temporary operational and maintenance issues that may be encountered at the Edward C. Little WRF or at the WCBB. Table H-5 presents the recycled water and imported water target volumes for the WCBB from 2010 through 2025. AWT recycled water is expected to fully replace imported water, with flow projected to increase to 17,000 AFY beginning WY 2013-14 and overall injection at the barrier is expected to be approximately 2,000 AFY higher by WY 2024-25 compared with the baseline period average.

2.4.2.3 Dominguez Gap Seawater Intrusion Barrier

The DGB began operating in 1971 and is currently comprised of 41 injection wells along the Dominguez Channel to the Harbor (110) Freeway in the City of Carson (Figure 2). The DGB is owned, operated, and maintained by the LACDPW. Currently, treated imported water from the SWP and/or CR supplied by MWD's Jensen and Diemer WTPs along with AWT recycled water from the City of Los Angeles' Terminal Island Water Reclamation Plant/Advanced Water Purification Facility (TIWRP) is delivered to the barrier for injection. The TIWRP capacity is currently 5,600 AFY.

Recycled water (AWT) was injected at the DGB beginning in February 2006. WRD purchases all the water injected at the DGB. The injection at the DGB is relatively evenly distributed amongst Model Layers 1, 2, and 3.

The baseline and future planning period volumes and sources of water injected at the DGB are summarized in Table H-5. During the baseline period, an average of about 7,000 AFY was injected/recharged at the DGB. AWT recycled water is projected to fully replace imported water for injection at the DGB in WY 2018-19 when the TIWRP is expanded to produce from 5,700 to 22,880 AFY of recycled water. Table H-5 presents the recycled water and imported water target volumes for the DGB from 2010 through 2025. AWT recycled water is expected to fully replace imported water, with flow projected to increase to 7,500 AFY beginning WY 2018-19 and overall injection is expected to be approximately 500 AFY higher by WY 2024-25 compared with the baseline period average.

2.4.3 Direct Percolation of Precipitation

The volume of precipitation that percolated to groundwater over the 10-year baseline period is based on estimates provided in the USGS/GBMP model (USGS, 2003; CH2MHILL, 2012b). The 10-year baseline period represents a range of precipitation conditions from very wet to very dry to normal. The model estimates are based on precipitation recorded at the LACDPW precipitation Station 107D located in the City of Downey, California. The model recharge values include the combined effects of mountain front recharge on the perimeter of the model domain and direct precipitation percolation, return flow from irrigation such as lawn watering, and other distributed negligible sources (i.e., leakage from pipes and septic systems) within the interior of the model domain. Because these individual components of the model recharge have different water quality with respect to S/N loading, estimates of each component's volume are accounted for separately in the SNMP analysis.

In order to separate out the various sources of recharge from the model estimated interior recharge, it is assumed that in very dry years, no precipitation or mountain front recharge occurs. In WY 2001-02, only 2.8 inches of precipitation were recorded at the Downey station. In that year, the model-generated interior recharge was about 14,500 AF. While about 14,500 AF of interior recharge was estimated in the model for WY 2001-02 for the entire model domain (including the Santa Monica and Hollywood model subareas outside of the CBWCB), only about 10,300 AF occurred within the CBWCB. For the SNMP study, this volume is assumed to represent sources other than deep percolation of precipitation and mountain front recharge, including return flow from irrigation and recharge at the DGSG (which was not accounted for separately in the model). Accordingly, this volume is subtracted from the model reported interior recharge for this study. **Table H-6** shows the volume of precipitation percolation in the Central Basin and West Coast Basin over the 10-year baseline period. Total average deep percolation over the 10-year baseline period is about 25,000 AFY in the CBWCB. Deep percolation of precipitation throughout the future planning period is assumed to be the average of the baseline period for each year from WY 2010-11 to 2024-25.

2.4.4 Mountain Front Recharge

Mountain front recharge is surface water runoff from the hills abutting the basins that recharges at the edges of the basins near the hills. The volumes of mountain front recharge estimated in the USGS/GBMP model in the Central Basin and West Coast Basin (assuming no mountain front recharge occurred in the driest WY [2001-02)]) are provided in **Table H-7**. The average mountain front recharge over the 10-year baseline period is about 9,000 AFY in the CBWCB. Mountain front recharge throughout the future planning period is assumed to be the average of the baseline period for each year from WY 2010-11 to 2024-25.

Table H-6 Volume of Precipitation Percolation in Central Basin and West Coast Basin

2.4.5 Irrigation Return Flows

Source waters for irrigation in the Study Area include imported water, groundwater, and recycled water. The volume of water used for irrigation in the Study Area is estimated to be 40%[7] of the total imported water and groundwater supply plus the approximate recycled water volumes used for irrigation. **Table H-8** shows the approximate total baseline and future planning period volumes of imported water and groundwater used for the entire water supply of the CBWCB; the volumes of imported water, groundwater, and recycled water used for irrigation; and the amount of applied irrigation water that percolates to groundwater in the CBWCB after evapotranspiration (ET).

Table H-8 presents the annual baseline and future planning period projected volumes of imported water used (including potable, irrigation, and industrial uses) in the Central Basin and West Coast Basin. The Draft 2012 GLAC IRWMP shows that water agencies in the CBWCB include imported water as an integral part of their water supply portfolios through 2025. For the Central Basin, per the Draft 2012 GLAC IRWMP, 121,000 AFY of imported water is expected to be used by 2025. This value represents a 13% decrease from WY 2009-10. This results in a decrease in the volume of imported water used for irrigation and recharged to groundwater in the Central Basin. For the South Bay Subregion, the Draft 2013 GLAC IRWMP shows a 2% increase in imported water use from 2010 to 2025. Applying this percent increase to West Coast Basin, a reasonable assumption is that 155,600 AFY of imported water would be used by 2025. This results in a slight increase in imported water use for irrigation and recharge to groundwater. However, the decrease in imported water use is much greater in the Central Basin than in the West Coast Basin, so overall irrigation return flows are predicted to decline for the entire CBWCB over the future planning period.

Table H-8 shows the annual total volumes of groundwater production from the Central Basin and West Coast Basin over the 10-year baseline period. Over this period, an average of about 196,600 AFY was extracted from the Central Basin and about 44,700 AFY from the West Coast Basin, which totals 241,300 AFY for the Study Area. For the future planning period, groundwater production in the CBWCB is assumed to be the average of the baseline period (Johnson, 2012). Therefore, irrigation return flows from groundwater use in the future planning period also remain the same as in the baseline period.

Use of recycled water for irrigation is projected to increase in the future planning period. Table H-8 shows the baseline period recycled water use for irrigation and the projected volume of recycled water use for irrigation for the future planning period. This recycled water would replace imported water and groundwater for irrigation.

Overall irrigation return flows in the Central Basin are projected to decrease slightly over the future planning period while return flows in the West Coast Basin are projected to increase slightly and thus, there is a net decline for the entire CBWCB (Table H-8).

---

[7] Estimate provided by Kathy Kunysz of the Metropolitan Water District of Southern California.

UWMP - Urban Water Management Plan

a - Total imported water minus imported water injected at the Alamitos Barrier and spread in Montebello Forebay for baseline period
b - Total imported water minus imported water injected at the Dominguez Gap and West Coast Basin barriers for baseline period
c - Data for baseline period from DWR, *Watermaster Service* Reports for Central and West Coast Basins, 2001 to 2011; reported in fiscal year; data for future planning period from Draft GLAC IRWMP (RMC, July 2012)
d - Baseline period data from WRD, Engineering Survey and Report , March 4, 2011; pumping in future planning period assumed to be the average of the baseline period per information provided by Ted Johnson, WRD, August 27, 2012
e - The significant voume of groundwater used for industrial supply in the West Coast Basin subtracted from total water used (see Secton 23.3.5 for explanation of calculation)
f - 40% of total water supply is assumed used for irrigation
g - Baseline data for calendar years 2001 through 2010 provided by Monica Gasca, SDLAC; information for the future planning period from Draft GLAC IRWMP (RMC, July 2012)
h - Baseline period information provided by Joe Walters, WBMWD, August 27, 2012 for use within the WBMWD service area; future planning period information provided in WBMWD 2010 UWMP (May 2011) and LADWP Non-Potable Reuse Master Planning Report (RMC, March 2012)
i - 3.6% of irrigation water percolates to groundwater (see Section 3.3.5 for explanation of 3.6% determination)
j - This is the increase or decrease between the average baseline period and Water Year 2024-25

In addition to its use for irrigation, recycled water is utilized for a variety of non-potable reuse (NPR) applications, including industrial uses; as a result, the total NPR volume is primarily comprised of these two specific usage volumes. For the SNMP, irrigation use is the primary target since it can contribute to salt and nutrient loading to the groundwater basins.

Information on total NPR and irrigation target volumes for the Central Basin was obtained from the 2012 Draft GLAC IRWMP and recycled water use data from SDLAC for calendar year 2001 through 2010. The 17,200 AFY of projected recycled water irrigation use in 2025 in the Central Basin, as shown in **Table H-9**, was based on the percentage of irrigation versus total NPR volumes in 2025 as shown in **Table H-10**.

Information on total NPR and irrigation target volumes for the West Coast Basin was obtained from the WBMWD 2010 UWMP (WBMWD, 2011) and the City of Los Angeles Department of Water and Power (LADWP) Non-Potable Reuse Master Planning Report (RMC, 2012a). Information was also provided directly from WBMWD and LADWP. The projected use of tertiary-treated recycled water (5,940 AFY) for irrigation in 2025 in the West Coast Basin, as shown in **Table H-11**, was derived based on information compiled in **Table H-12**.

2.4.6 Other Stream Recharge

As shown in Figure 2, major streams in the Study Area are mostly lined with concrete. Because of this, stream losses to groundwater are assumed to be negligible, except for recharge in the unlined portion of the San Gabriel River within the Montebello Forebay, which is accounted for in the Montello Forebay spreading operations, as discussed in Section 2.3.1.1. This assumption is consistent with the USGS/GBMP modeling water balances, which also assumed river recharge/discharge was minimal.

2.4.7 Other Distributed Sources of Recharge

Other areally distributed potential sources of recharge included leaking water and sewer pipes, stormwater capture facilities such as basins and LID projects, and septic systems. While not individually quantified in the USGS/GBMP model or for the SNMP study, these distributed sources are represented in the USGS/GBMP model's interior recharge volumes.

The City of Torrance operates a number of stormwater retention basins, some of which (the Bishop Montgomery, Del Amo and Ocean Basins) allow for stormwater replenishment. The volumes of stormwater percolated are not available, but are not considered to be significant recharge inputs for the SNMP loading analysis.

Siempre Agua is a proposed project that will create a 2-acre wetland that will use 88 AFY of Los Angeles River water. It will be located in the northernmost portion the Central Basin and implemented in the next few years[8]. It is not known at this time if the wetland will be lined or unlined, but once the wetland is created and operational, approximately 80 AF of the treated wetland water will be used to irrigate a park (effective percolation from irrigation of 4

NPR – no-potable reuse
AFY – acre-feet per year
SDLAC – Sanitation Districts of Los Angeles County
SNMP – Salt and Nutrient Management Plan

a - Historic data for calendar years 2001 through 2010 provided by Monica Gasca, SDLAC

b - For purposes of estimating projected use of recycled water for irrigation, a linear extrapolation was applied to the Δ 9,600 AFY (see Table H-10) from 2010 to 2025; industrial projections were not derived because they are not necessary for the SNMP assessments

c - As shown in Table H-10, this is the projected total NPR use

Table H-10 Basis for Irrigation Target Volumes in the Central Basin

Year	Recycled Water Usage	Volume (AFY)	Type of Recycled Water
2010	Total NPR	9,700 [a]	Tertiary-treated
	Irrigation	7,600 [a]	Tertiary-treated
	% Irrigation	**78%**	**Tertiary-treated**
2025	Total Projected NPR [b]	22,100	Tertiary-treated
	Estimated Irrigation [c]	17,200	Tertiary-treated
	% Irrigation	**≈ 78%**	**Tertiary-treated**
Δ 2025 [d]	**Irrigation**	**9,600**	**Tertiary-treated**

AFY – acre-feet per year
SDLAC – Sanitation Districts of Los Angeles County
MWD – Municipal Water District
NPR – non-potable reuse
WY – water year
UWMP – Urban Water Management Plan
GLAC IRWMP – Greater Los Angeles County Integrated Regional Water Management Plan

a - Information provided by Monica Gasca, SDLAC; this represents 10-year average (2001 - 2010)

b - This value was derived from the 2025 target volumes in the Central Basin MWD 2010 UWMP (11,000 AFY) as reflected in the 2012 Draft GLAC IRWMP, the Long Beach 2010 UWMP (8,100 AFY) as reflected in the 2012 Draft GLAC IRWMP, and the four-year averages (WY 2006-07 through 2009-10) for the City of Lakewood (440 AFY) and City of Cerritos (2,600 AFY) from the SDLAC Annual Status Reports on Recycled Water

c - Assumes there will be no substantive change in the proportion of recycled water used for irrigation between 2010 and 2025, and thus approximately 78% of the total NPR was used to derive the amount of irrigation (22,100 AFY x 0.78 = 17,200 AFY)

d - This is the increase in recycled water irrigation use between WY 2010-11 and 2024-25

Table H-11 Baseline Period Recycled Water NPR and Future Planning Period Target Volumes for Irrigation in the West Coast Basin

NPR – non-potable reuse
AFY – acre-feet per year
SNMP – Salt and Nutrient Management Plan
WBMWD – West Basin Municipal Water District
LADWP – City of Los Angeles Department of Water and Power
AWT – advanced water treatment

a - For 2001 – 2010, historical information within the WBMWD service area was provided by Joe Walters, WBMWD, August 27, 2012 for WBMWD's service area

b - Estimate for LADWP's West Side service area for irrigation provided by Todd Rother, LADWP (LADWP 2012 Non-Potable Reuse Master Planning Report)

c - For purposes of estimating projected use of recycled water for irrigation, a linear extrapolation was applied to the Δ 1,800 AFY of tertiary-treated recycled water supplied to the West Coast Basin from 2010 to 2025 as shown in Table H-12. For the Δ 160 AFY of AWT recycled water supplied by LADWP, it will be assumed that this use starts in 2025; total NPR projections were not derived because they are not necessary for the SNMP assessments

d- See Table H-12 for derivation of 2025 target volumes

Table H-12 Basis for Recycled Water Irrigation Target Volumes in the West Coast Basin

Year	Recycled Water Usage	Volume (AFY)	Type of Recycled Water
2010	Total NPR [a]	21,080	Tertiary-treated
	Irrigation in WBMWD Service Area	3,880	Tertiary-treated
	Irrigation in LADWP Service Area	0	None
	Total Irrigation	3,880	Tertiary-treated
2025	WBMWD Service Area LADWP Westside Service Area Total Projected NPR [b]	33,900 10,120 44,020	Tertiary-treated and AWT
	Estimated Irrigation in WBMWD Service Area [c]	5,100	Tertiary-treated
	Estimated Irrigation in LADWP Service Area [d]	540	Tertiary-treated
	Total Estimated Irrigation	5,640	Tertiary-treated
	Estimated Irrigation in LADWP Service Area [e]	160	AWT
	Total Estimated Irrigation in 2025	5,800	Tertiary-treated and AWT
Δ 2025 [f]	**Irrigation**	**1,800 [g]**	**Tertiary-treated**
		160	**AWT**

WBMWD – West Basin Municipal Water District
LADWP – Los Angeles County Department of Water and Power
WRF – Water Reclamation Facility
UWMP – Urban Water Management Plan
TIWRP – Terminal Island Water Reclamation Plant/Advanced Water Purification Facility
AFY – acre-feet per year
WY – water year
NPR – non-potable reuse
AWT – advanced water treatment

a - Estimated demand volumes within the WBMWD service area are based on information provided by Uzi Daniel, WBMWD (the 10-year average from 2001 to 2010 as shown in Table H-8; demand volumes within the LADWP service area assume there is a negligible amount of irrigation supplied by the TIWRP and 880 AFY of total NPR supplied by WBMWD to LADWP's West Side service area for irrigation; information regarding LADWP's service area was provided by Todd Rother, LADWP (LADWP 2012 Non-Potable Reuse Master Planning Report)

b - Estimated demand volumes within the WBMWD service area were derived from the 2025 target in the 2010 WBMWD UWMP (33,900 AFY); demands within the LADWP service area are based on the LADWP 2012 Non-potable Reuse Master Planning Report; assuming that 'planned projects' will be online by 2025, there will be 210 AFY of Total NPR supplied from TIWRP, 9,910 AFY from WBMWD's Edward C. Little WRF, for a total of 10,120 AFY inside LADWP's service area.

c - This volume assumes there will be no substantive change in the proportion of recycled water used for irrigation by WBMWD in its service area and LADWP's Westside service area between 2010 and 2025; for 2010, the WBWMD % irrigation = WBMWD service area irrigation 3,000 AFY/total NPR 20,200 AFY = 15%; thus, approximately 15% of WBMWD's 2025 total NPR (33,900 AFY) was used to derive the amount of irrigation (33,900 AFY x 0.15 = 5,100 AFY); information was provided by Uzi Daniel, WBMWD

d - This value for irrigation is obtained from the LADWP 2012 Non-Potable Reuse Master Planning Report; it includes 540 AFY of tertiary-treated recycled water supplied from WBMWD's Edward C. Little WRF; this use starts in 2025

e - This value is obtained from the LADWP 2012 Non-Potable Reuse Master Planning Report and Todd Rother, LADWP; it includes 160 AFY of AWT recycled water from the TIWRP; this use starts in 2025

f - This is the increase in recycled water irrigation use between WY 2010-11 and 2024-25

g - This value is based on 5,640 AFY minus 3,880 AFY, which equals 1,760 AFY, rounded off to 1,800 AFY

AF/year)[9]. Because water in wetland generally does not percolate into groundwater due to the silty muddy bottoms even if unlined, and the park irrigation is very small, the project is not considered a significant recharge component for the SNMP loading analysis.

Of the distributed sources, only sewer line leakage and septic system losses would have significantly different water quality than precipitation infiltration and irrigations return flows, as discussed above. Cities and agencies in the CBWCB, including the City of Los Angeles Bureau of Sanitation (LABOS) and SDLAC, generally have inspection and maintenance programs in place to quickly identify and fix any leaking sewer lines. For this reason, sewer line leakage is assumed to be negligible in terms of the overall S/N loading assumptions. Similarly, SDLAC has indicated that there are only a small number of parcels (478 parcels of approximately 859,500 parcels in the Study Area) currently relying on septic systems for wastewater handling. Accordingly, septic system recharge to groundwater in the CBWCB is assumed to be negligible.

2.4.8 Subsurface Groundwater Inflow from Adjacent Basins and Ocean

Because of the pumping depressions in the Study Area, subsurface groundwater from adjacent basins (Santa Monica, Hollywood, San Fernando, San Gabriel, and Orange County basins) and the ocean (Santa Monica Bay and San Pedro Bay) flows into and recharges the CBWCB. The locations of adjacent basins are shown in Figure 1. Groundwater also flows between the Central Basin subareas and between the Central Basin and West Coast Basin. Subsurface inflows for the 10-year baseline period were extracted from the USGS/GBMP model. **Table H-13** provides a summary of theses volumes. The average subsurface inflow over the 10-year baseline period is about 41,400 AFY in the Central Basin and about 12,600 AFY in the West Coast Basin. Throughout the future planning period, annual subsurface inflows and outflows are assumed to be the average of the baseline period.

2.5 Groundwater Discharge (Outflows)

Groundwater can leave the CBWCB by:

- Pumping, including extraction associated with the desalters,
- Subsurface outflow to adjacent basins and the ocean, and
- Groundwater discharge to surface water.

Of these, groundwater pumping is the most significant outflow from both the Central Basin and West Coast Basin. Due to the large pumping depressions in both basins, very little groundwater leaves the Study Area as subsurface outflow and while there is some outflow to adjacent areas, the overall net subsurface flow is into the Study Area. Similarly, as discussed above, because most streams are concrete-lined, there is little opportunity for groundwater discharge to surface water and thus, this source of discharge is assumed to be negligible.

2.5.1 Groundwater Pumping and Desalters

Groundwater production wells are the main source of groundwater extraction and usage in the CBWCB. There are currently over 400 active production wells in the CBWCB. Prior to the adjudication of the groundwater basins in the early 1960s, annual production (pumping) reached levels as high as 292,000 AF in the Central Basin and 94,000 AF in the West Coast Basin. Figure 35 shows groundwater production in the Study Area in WY 2009-10. A production map for each water year is presented in the annual *Engineering Survey and Report* prepared by WRD. The different size and color circles on the figure represent relative volumes of annual pumping. The figure shows that there are more wells and more pumping in the Central Basin than in the West Coast Basin. Production in the Central Basin is fairly well distributed. Pumping in the West Coast Basin is clustered inland of the DGB and the WCBB. Figure 36 is a chart showing historical groundwater production in the CBWCB. The chart shows a slight declining trend in groundwater production since 1960.

Table H-8 shows the annual baseline and future planning period volumes of groundwater production in the Central Basin and West Coast Basin. Over the baseline period, an average of about 196,600 AFY was extracted from the Central Basin and about 44,700 AFY from the West Coast Basin, thus totaling 241,300 AFY for both basins. Throughout the future planning period, annual groundwater production is assumed to be at the average of the baseline period (Johnson, August 2012).

There are two desalters operating in the West Coast Basin, specifically in the City of Torrance. The desalters remove salt (using reverse osmosis membranes) from seawater-impacted groundwater and the treated water is distributed for potable supply. The C. Marvin Brewer Desalter (Brewer Desalter), with a design capacity of 1,200 AFY, is owned by WBMWD and operated by California Water Service Company, who distributes the treated water to their drinking water system. The Robert W. Goldsworthy Desalter (Goldsworthy Desalter), with a design capacity of 2,800 AFY, is owned by WRD and operated and maintained by the City of Torrance, who distributes the treated water to their drinking water system. **Table H-14** shows baseline and projected desalter pumping. Annual pumping from WY 2000-2001 to 2011-2012 for both desalters were obtained from the WRD groundwater production database. WRD (verbal communication, Jim McDavid) provided estimated pumping for the Goldsworthy Desalter from WY 2012-2013 to 2013-2014. In 2015, the total plant capacity of the Goldsworthy Desalter will be expanded to 5,500 AFY[10] to allow increased groundwater pump and treat. The remaining estimated future planning period (from WY 2012-2013 to 2024-2025) volume of groundwater pumped annually for the Brewer Desalter is the average of the last five years of reported pumping (i.e. WY 2007-08 through 2011-12), which is an increase from the average baseline pumping. This five year averaging period was selected rather than the baseline period average to account for the lack of pumping from WY 2003-2004 to 2005-2006. The baseline and future planning period pumping volumes from wells associated with the desalters are included in the production listed in Table H-8 and because the desalters remove salt from groundwater, they are also accounted for separately in Table H-14.

[10] Personal communication from Ted Johnson, November 14, 2012.

2.6 Overall Water Balance and Change in Groundwater Storage

Component-specific water balances were developed based on water balances presented in the USGS/GBMP modeling reports. **Table H-15** presents a summary of the overall baseline period water balance for the Central Basin and **Table H-16** presents the overall baseline period water balance for the West Coast Basin. The tables also provide the annual and cumulative change in groundwater storage. Water balances are extracted from the USGS/GBMP groundwater model and due to rounding errors, model gridding, distribution of flows into and out of different model layers, and other affects, the model-generated numbers are slightly different than the values indicated in the tables presented in this appendix. Differences are less than 1% and are within the margin of error of the table values. As an example, it is noted that while recharge from irrigation return flows in the CBWCB for WY 2001-02 (8,900 AF) was the basis for estimating the irrigation return flow percentage, application of the 3.6% return flow percentage to WY 2001-02 irrigation volumes for the Central Basin and West Coast Basin individually results in irrigation return flow volumes for each basin (approximately 6,000 AF in the Central Basin and 2,900 AFY in the West Coast Basin) that differ slightly from volumes in the numerical model (approximately 6,300 AF in the Central Basin and 2,600 AF in the West Coast Basin). These differences are considered to be insignificant as the differences result in a deviation of less than 1% over the baseline period in each of the two basins.

Figure 6 illustrates the baseline period annual water balances and cumulative change in groundwater storage. The Central Basin water balance is shown on the top of the figure and the West Coast Basin water balance is depicted on the bottom of the figure. As shown in Figure 6, the MFSG (with minor contributions from the DGSG) recharge is the largest inflow to the Central Basin followed by subsurface inflow, deep percolation of precipitation, mountain front recharge, irrigation return flows, and the AGB injection. Groundwater pumping is the major outflow along with a small amount of subsurface outflow to the West Coast Basin. Any other types of inflows or outflows from the basin were negligible and therefore, are not listed in Tables H-15 or H-16. Annual change in storage varies considerably from year to year, with an overall negative cumulative change (i.e., loss) in storage over the 10-year baseline period.

As depicted in Figure 6, in the West Coast Basin, the seawater intrusion barriers (WCBB and DGB) are the largest source of recharge; subsurface inflow from adjacent basins with a small amount from the ocean also provide significant recharge followed by deep percolation of precipitation. Smaller components of recharge include irrigation return flows, mountain front recharge, and the DGSG. As with the Central Basin, annual change in groundwater storage can vary from year to year. Groundwater pumping is the only outflow as there is no subsurface outflow. The cumulative change in storage in the West Coast Basin over the SNMP baseline period is positive, thus indicating an increase.

WRD also calculates the basins' change in storage annually with a method not based on the water balance. WRD uses groundwater levels to determine when additional replenishment water is required and to calculate groundwater annual and cumulative change in storage. These data are presented in WRD's annual *Engineering Survey and Report* (accessed at: http://www.wrd.org/engineering/groundwater-engineering-reports.php). This method is different than the water balance method presented in this appendix and as a result, the

Negative values indicate a loss or reduction

Water balances are extracted from USGS/GBMP groundwater model and due to rounding errors, model gridding, distribution of flows into and out of different model layers, and other affects, the model-generated numbers are slightly different than supporting tables; differences are less than 1% and are within the margin of error of the supporting number estimates.

approximate changes in storage presented in Tables H-15 and H-6 may not exactly match numbers presented in the *Engineering Survey and Report.* Two future planning period water balance scenarios are presented as Figure 7 (No Future Projects Scenario) and Figure 8 (All Projects Scenario). The No Future Projects Scenario water balances assume that average baseline period inflows and outflows continue for every year of the future planning period with no changes (i.e. no new projects implemented, just continuation of existing projects). The All Projects Scenario water balances assume that all future projected changes in inflows and outflows described in this appendix are implemented, including increased recharge at the MFSG, DGSG, and seawater intrusion barriers, slightly decreased irrigation return flow in the Central Basin, slightly increased irrigation return flow in the West Coast Basin, and increased pumping for the desalters. Other inflows and outflows, including precipitation return flow, mountain front recharge, and subsurface flows are maintained at the average baseline period volumes for each year of the future planning period. The No Future Projects Scenario water balances are needed so that the S/N impacts from the various proposed projects can be compared with a scenario where S/N loading and unloading remains at average baseline conditions. Refer to Appendix I *Simulated Baseline and Future Salt and Nutrient Groundwater Quality* for further discussion of S/N impacts from proposed projects. As with the baseline period water balances, it is noted that volumes for certain inflows and outflows extracted from the USGS/GBMP groundwater model vary slightly from those indicated in the tables presented in this appendix. This occurred as a result of numerical rounding during apportionment of certain flows into and out of the various model mixing volumes (basins/subareas/layers) and other affects. Differences are less than 1% and are within the margin of error of the numbers presented in the tables.

The No Future Projects Scenario water balances for the Central Basin and West Coast Basin for the future planning period are presented in **Tables H-17** and **H-18**, respectively, and Figure7. Average baseline period inflows and outflows were duplicated for each year from WY 2010-11 through 2024-25. By 2025 in the Central Basin, there is an annual loss of storage of about 6,100 acre-feet (AF) and a cumulative loss in storage (over the future planning period) of approximately 92,000 AF. By 2025 in the West Coast Basin, there is an annual gain in storage of about 2,300 AF and a cumulative gain in storage (over the future planning period) of approximately 34,000 AF.

The water balances for the All Projects Scenario, which include the combined future changes discussed above, are presented in **Tables H-19** and **H-20**, respectively, and Figure 8. Average baseline period inflows and outflows are duplicated for each year from WY 2010-11 through 2024-25 and projected future changes (due to implementation of proposed projects) are superimposed on this average baseline condition. In comparison with the No Future Projects Scenario, the All Projects Scenario recharges additional water to the basins. By 2025 in the Central Basin, there is an average annual gain in storage of about 1,500 AF and a cumulative increase in storage (over the future planning period) of approximately 22,400 AF. By 2025 in the West Coast Basin, there is an average annual gain in storage of about 2,600 AF and a cumulative increase in storage (over the future planning period) of approximately 38,500 AF.

Negative values indicate a loss or reduction

a - Includes average annual groundwater production over baseline period plus net additional annual groundwater pumping from desalter wells

3 Future Groundwater Levels

Given the projected increase in storage over the future planning period for the All Projects Scenario, groundwater levels are expected to rise in the future. In order to estimate the change in groundwater levels, CH2MHILL incorporated into the existing USGS/GBMP groundwater flow model the estimated annual water budget projections developed for the No Future Projects Scenario and All Projects Scenario and simulated the groundwater level response for both scenarios from WY 2010-11 through 2024-25. Figure 37 shows the simulated groundwater level change (from WY 2010-11 to 2024-25) within the four model layers for the All Projects Scenario. The map was generated by subtracting the WY 2010-11 simulated groundwater elevation from the WY 2024-25 simulated groundwater elevation for the All Projects Scenario for each model grid cell within each model layer. Figure 37 shows that simulated groundwater elevations in all model layers increase over the 15-year future planning period across much of the CBWCB with the exception of the Los Angeles Forebay, in which varying degrees of groundwater level decline are predicted in Model Layers 2 through 4 due to groundwater production in these layers. In order to quantify the groundwater level impact of planned projects included in the All Projects Scenario, a separate map (Figure 38) was prepared showing the difference between WY 2024-25 groundwater levels for the All Projects Scenario versus WY 2024-25 groundwater levels for the No Future Projects Scenario. Figure 38 shows that the increase in groundwater recharge from the planned projects have a significant positive impact (i.e., increase) on groundwater levels across the CBWCB compared to the No Future Projects Scenario over the 15-year future planning period.

1 Introduction

This Appendix I describes the simulated baseline and future salt and nutrient (S/N) groundwater quality for the Central Basin and West Coast Basin (CBWCB or Study Area). Key components of this appendix include:

- Description of major projects to be implemented during the future planning period (Water Year [WY] 2010-11 to 2024-25) that affect S/N loading,
- Estimation of baseline period (WY 2000-01 to 2009-10) and future planning period S/N mass balances (basin inflows and outflows),
- Description of the mixing model that was developed to estimate future groundwater quality,
- Simulation of baseline and future planning period S/N groundwater quality using the mixing model,
- Calculation of impacts on groundwater quality due to proposed major recycled water projects and use of available assimilative capacity, and
- An anti-degradation analysis of the CBWCB.

Section 2 describes the mixing model that was developed to estimate future water quality and the scenarios that were simulated by the mixing model. Section 3 presents an analysis of historical S/N groundwater quality trends. Section 4 describes the baseline and future S/N balances. Section 5 describes the baseline and future groundwater quality and use of the available assimilative capacity by existing and planned major recycled water projects. Section 6 presents the anti-degradation analysis.

Attachment I-A provides a description of the Mann-Kendall statistical trend test used to assess historical groundwater quality trends. Attachment I-B presents total dissolved solids (TDS), chloride, and nitrate time-concentration plots for Water Replenishment District of Southern California (WRD) nested groundwater monitoring wells. Attachment I-C presents baseline and future S/N balance tables. Attachment I-D provides figures showing projections for future groundwater quality through WY 2049-50 for TDS, chloride, and nitrate.

References cited in this appendix and other appendices are provided at the end of the Salt and Nutrient Management Plan (SNMP).

2 SNMP Mixing Model and Simulation of Groundwater Quality

An SNMP mixing model was developed to simulate future planning period groundwater quality and evaluate the effects of planned future projects on overall groundwater quality in the CBWCB through WY 2024-25. This mixing model was developed in Microsoft Excel™ and is effectively a set of linked spreadsheets used to represent “continuously-stirred” mixing volumes. At the request of Los Angeles Regional Water Quality Control Board (LARWQCB), these spreadsheets were provided to the LARWQCB in October 2013. The mixing model was designed to: 1) account for the current groundwater volume and S/N mass in storage within the CBWCB, and 2) track the loading/unloading of S/Ns through major groundwater sources and sinks under current (baseline period) and future land use/water use conditions (various scenarios for the future planning period).

The estimated current groundwater volume (provided by the MODFLOW regional groundwater flow model that was developed by the United States Geological Survey [USGS] in 2003 and was recently updated for the Groundwater Basins Master Plan [GBMP]) and associated S/N mass in storage (concentrations provided by estimated existing average S/N groundwater quality) within the CBWCB served as initial inputs into the mixing model. Consideration of the groundwater volume and S/N mass in storage is necessary for predicting future groundwater quality concentrations in order to compare simulated concentrations with Basin Plan Objectives (BPOs) and anti-degradation thresholds (assimilative capacity) defined by the Recycled Water Policy. In recognition of the variable hydrogeologic and groundwater quality conditions and different BPOs established for the Central Basin and West Coast Basin, the CBWCB was divided into discrete mixing volumes (subareas/layers) in the SNMP mixing model.

The effect of S/N loading on groundwater quality is predicated on the following understanding that groundwater quality: 1) improves if the flow-weighted concentration of all inflows (or mass) is less than the flow-weighted concentration (or mass) of all outflows, 2) degrades if the flow-weighted concentration of all inflows (or mass) is greater than the flow-weighted concentration (or mass) of all outflows, or 3) remains unchanged if flow-weighted concentration (or mass) of all inflows equals the flow-weighted concentration (or mass) of all outflows.

The S/N inflows and outflows were mixed with the existing groundwater volume and quality using the mixing model and groundwater concentrations were estimated for each year of the baseline and future planning periods. The simulated baseline concentrations were compared with the dominant actual observed groundwater quality trends. Based on the comparison, inflow and outflow concentrations were adjusted to achieve a better match to observed concentrations. For the future planning period, several different scenarios were simulated as described in Section 2.3 *Scenarios Simulated to Estimate Future Groundwater Quality*.

2.1 Mixing Model Calibration

To address the uncertainty in estimating S/N loading for each individual S/N source, the baseline period (WY 2000-01 through 2009-10) was used to compare simulated concentration trends against observed concentration trends on a basin/subarea-scale, identify S/N loading factors with the highest level of significance, and of those factors, modify the ones with the highest level of uncertainty to provide a reasonable match between observed and simulated concentrations.

Regional observed concentration trends were measured by performing the Mann-Kendall statistical trend test as described in Section 3 *Groundwater Quality Trend Analysis*. On a basin/subarea-scale, initial simulation results (groundwater concentrations and annual concentration trends within a given subarea/basin) were compared to observed background concentrations and concentrations trends over the baseline period to determine the sensitivity of the model to individual S/N loads. Loading factors with higher levels of uncertainty were refined until simulated results best matched observed concentrations and concentration trends on a basin/subarea-wide basis. With the exception of refinement of nitrate loading associated with operations at the Montebello Forebay Spreading Grounds (see adjustment No. 3 below), all refinements to key loading assumptions in the mixing model were applied across the entire CBWCB and not selectively applied to individual subareas or layers. Following several iterations, the following adjustments to key S/N loading estimates were incorporated into the final calibrated mixing model:

Initial simulation results indicated that TDS and chloride loading were underestimated across the CBWCB (resulting in declining TDS/chloride concentration trends over the baseline period not in agreement with observed groundwater quality trends). One key TDS loading factor with relatively high uncertainty is the evaporation/concentration effect of applied irrigation water. An initial evaporation/concentration factor of three was applied to TDS and chloride in irrigation return flow (i.e. 300% of applied irrigated water concentration was assumed for return flows). However, preliminary simulation results indicated the use of a higher evaporation/concentration factor was warranted. To better reflect the TDS and chloride trends observed in the CBWCB, an evaporation/concentration factor of nine (i.e. 900%) was applied to TDS and chloride concentrations in applied irrigation water. This resulted in an average irrigation return flow of 4,100 mg/L of TDS and 381 mg/L of chloride in the Central Basin and 3,363 mg/L of TDS and 827 mg/L of chloride in the West Coast Basin (for imported water and groundwater).

Comparison of initial simulated groundwater nitrate concentrations across the CBWCB to actual observed groundwater nitrate concentrations indicated that either: 1) nitrate concentrations in irrigation return flow (with fertilizer added) were overestimated or 2) additional nitrate attenuation in the vadose zone was not captured in the mixing model. To account for the attenuation of nitrate and to match actual observed groundwater quality concentrations and trends, nitrate-N concentrations in irrigation return flow were reduced by a factor of 10% (i.e. 90% attenuation).

Comparison of initial simulated and background nitrate-N or NO_3-N concentrations in groundwater and trends within the Montebello Forebay indicated that measurable nitrate attenuation occurs beneath the Montebello Forebay Spreading Grounds (MFSG). To match the observed groundwater quality in this critical area, the following nitrate attenuation factors were applied to MFSG blended recharge water quality and respective vertical and horizontal subsurface groundwater flows beneath the Montebello Forebay:

- MFSG water quality to Model Layer 1 = 84% of NO_3-N (16% attenuation)
- From Model Layer 1 to Layer 2 in Montebello Forebay = 100% of NO_3-N (no attenuation)
- From Model Layer 2 to Layer 3 in Montebello Forebay = 62% of NO_3-N (38% attenuation)
- From Model Layer 3 to Layer 4 in Montebello Forebay = 0% of NO_3-N (100% attenuation)
- From Model Layer 1 in Montebello Forebay to Model Layer 1 in Central Basin Pressure Area = 6% of NO_3-N (94% attenuation).

To account for mineral dissolution along rainfall recharge flowpaths, a constant concentration of 150 mg/L for TDS and 20 mg/L for chloride was applied to recharge related to deep percolation of precipitation. This level of increase allowed for a better match between simulated and actual observed concentrations. The annual nitrate-N concentration in raw precipitation was applied directly to deep percolation of precipitation.

2.2 Mixing Model Assumptions

The primary assumption of the SNMP mixing model is that S/N mixing within a given mixing volume is complete during each annual time step. While the CBWCB is divided into 20 mixing volumes (i.e., subareas/layers) to account for variable loading and non-uniform concentrations across the basins, it is recognized that the assumption of complete mixing can result in two potential errors: 1) overestimation or underestimation of the S/N concentration assigned to subsurface flows between discreet neighboring volumes, and 2) overestimation of the effect of S/N loading changes associated with a point-source projects in one mixing volume on neighboring mixing volumes. The effect of the two potential errors on vertical S/N transport between mixing volumes (e.g., Layer 1 to Layer 2 in a given subarea) is limited for two reasons: 1) vertical flows are generally fairly consistent across each basin/subarea; therefore, the volume-weighted average concentration for each model layer is a representative concentration for vertical S/N fluxes, and 2) insofar as S/Ns migrate vertically but are maintained in a respective basin/subarea, they do not affect the volume-weighted average concentration for that basin/subarea.

Examination of concentration contour maps and future simulation results indicate that the two potential errors associated with the assumption of complete S/N mixing within mixing volumes likely contributed to the slight overestimation of the TDS and chloride concentrations assigned to horizontal subsurface flowpaths (e.g., Layer 1 to adjacent subarea Layer 1; Layer 2 to adjacent subarea Layer 2, etc.) from the Los Angeles Forebay, Montebello Forebay, and Whittier Area to the Central Basin Pressure Area. These errors resulted in a conservative overestimation of groundwater quality for the Central Basin Pressure Area and help to explain partly why this subarea is projected to experience the highest concentration increase and the greatest use of current available assimilative capacity with respect to TDS and chloride.

Simulation results also indicate that some of the projected TDS and chloride concentration increases in the Central Basin Pressure Area were caused by two local factors: 1) loading from irrigation return flows within the Central Basin Pressure Area, and 2) limited unloading from pumping; most of the pumping in the Central Basin Pressure Area is by wells screened in Model Layer 3, which has lower TDS and chloride concentrations compared to the subarea volume-weighted average concentration for all layers. In addition to these two factors, some of the TDS and chloride concentration increases in the Central Basin Pressure Area are also a result of S/N loading associated with subsurface inflows from the Los Angeles Forebay, Montebello Forebay, and Whittier Area. Volume-weighted average TDS and chloride concentrations are higher in these upgradient areas than in the Central Basin Pressure Area. However, concentration contour maps indicate that the volume-weighted average TDS and chloride concentrations in Model Layers 2 and 3 in the Los Angeles Forebay and Whittier Area are higher than respective concentrations along the boundary shared with the Central Pressure Area. Thus, S/N fluxes along these boundaries are slightly overestimated.

2.3 Scenarios Simulated to Estimate Future Groundwater Quality

For the SNMP future planning period, several changes in the future water and S/N balances are anticipated due to the implementation of proposed projects in the CBWCB. Appendix H *Baseline and Future Water Balances* identifies baseline period (WY 2000-01 through 2009-10) and future planning period (WY 2010-11 through 2024-25) water balances for groundwater, imported water, and recycled water use; stormwater capture; and all other basin inflows and outflows. **Table I-1** summarizes the major proposed projects or "scenarios" that were simulated by the SNMP mixing model to determine future water quality and assess assimilative capacity impacts.

As shown in Table I-1, a total of 11 scenarios were simulated by the SNMP mixing model and results from the simulations were compared to Scenario 1 (i.e. continued baseline period average conditions in the future). Scenarios 1 through 7 were assessed to determine water quality impacts of individual projects in isolation. In reality, some combination of these projects will be implemented in the future planning period, so Scenarios 8 through 11 were simulated to assess the impacts of various combinations of projects. As described in Table I-1, Scenarios 8 through 11 also include the following minor future changes:

- Decreased imported water use for supply in the Central Basin (from a baseline period average of 129,300 acre-feet per year (AFY) to about 121,000 AFY by WY 2024-25) and slightly increased imported water for supply in the West Coast Basin (from a baseline period average of about 143,000 AFY to about 155,600 AFY by WY 2024-25). This results in a net decrease in imported water supply in the CBWCB and a reduction in S/N loading from irrigation return flows.
- Increased stormwater capture at the Dominguez Gap Spreading Grounds (DGSG) from a baseline period average of about 760 AFY to about 1,760 AFY by WY 2017-18.

During the future planning period, a recycled water project under WRD's Groundwater Reliability Improvement Program (GRIP) is expected to be implemented to supply increased tertiary-treated recycled water and/or advanced treated recycled water for recharge at the MFSG to completely replace imported water (up to 21,000 AFY). Two alternatives, GRIP Recycled Water Project A (GRIP A) and GRIP Recycled Water Project B (GRIP B) (Scenarios 6 and 7, respectively) described in Table I-1 are the end result of many studies conducted over a number of years to assess multiple potential projects to improve water supply reliability in the face of imported water supply uncertainties and increasing costs. These studies evaluated a wide spectrum of projects, including consideration of different levels of recycled water treatment and blending, modifications to existing wastewater treatment facilities, continued imported water deliveries, alternative imported water supplies, desalination, and increased stormwater capture (MWH, 2009a through 2009l; RMC, 2011b; SDLAC, 2012; and CH2MHILL, 2012c). GRIP A and GRIP B were determined to be the best alternatives for implementation and thus, potential water quality impacts for both scenarios were simulated by the SNMP mixing model.

Table I-1 Description of Scenarios Simulated by the SNMP Mixing Model

Scenario No.	Description
1	**No Future Projects** – Average of baseline period conditions (i.e. continuation of only existing projects and no implementation of proposed projects) reproduced for each year of the future planning period (Water Year [WY] 2010-11 through 2024-25).
2	**Increased Recycled Water for Irrigation (Baseline Period Average Water Quality)** – This is a proposed project in the Central Basin and West Coast Basin (CBWCB) that would increase the use of recycled water for irrigation (replacing imported water and groundwater). Recycled water used for irrigation is anticipated to increase from the 10-year baseline period (WY 2000-01 through 20009-10) average of about 10,600 acre-feet per year (AFY) to about 23,100 AFY by WY 2024-25. For this scenario, recycled water quality for salt and nutrients (S/Ns) is equivalent to the baseline period average (see Table I-9). For the CBWCB Salt and Nutrient Management Plan (SNMP), S/Ns specifically refers to nitrate as nitrogen (nitrate-N), total dissolved solids (TDS), and chloride.
3	**Increased Recycled Water for Irrigation (Water Quality Equivalent to MCL/SMCLs)** – This is a proposed project in the CBWCB that would increase the use of recycled water for irrigation (replacing imported water and groundwater). Recycled water used for irrigation is anticipated to increase from a baseline period average of about 10,600 AFY to about 23,100 AFY by WY 2024-25. For this scenario, recycled water quality is equivalent to: • Nitrate-N – Primary Maximum Contaminant Level (MCL) of 10 milligrams per liter (mg/L), • TDS – Secondary Maximum Contaminant Level (SMCL) of 1,000 mg/L, and • Chloride – SMCL of 500 mg/L. These recycled water concentrations are higher than the baseline period averages (Scenario 2). Currently, permitted recycled water quality limits established for non-potable reuse (irrigation, industrial and recreational activities) are generally more conservative than the SMCLs established for TDS and chloride.
4	**Seawater Intrusion Barriers** – This scenario consists of planned projects that would increase injection volumes and increase the use of recycled water that has undergone advanced water treatment (AWT) to completely replace imported water at the West Coast Basin Seawater Intrusion Barrier (WCBB), Alamitos Gap Seawater Intrusion Barrier (AGB), and Dominguez Gap Seawater Intrusion Barrier (DGB). Total AWT recycled water used for injection at the barriers is anticipated to increase from a baseline period average of about 9,500 AFY to about 31,700 AFY by WY 2018-19. The switch to AWT recycled water from imported water significantly reduces TDS and chloride in the recharge water (changes in nitrate concentrations are not significant). As a result, these planned seawater barrier projects were designated as an implementation measure, as further discussed in Appendix J in the SNMP.

Scenario No.	Description
5	**Increased Groundwater Pump and Treat by the Desalters in the West Coast Basin** – This scenario consists of planned projects that would increase the amount of groundwater pumped and treated by the two existing desalter facilities in the West Coast Basin. The Robert W. Goldsworthy Desalter will be expanded and the associated groundwater pumping will increase from a baseline period average of about 1,900 AFY to about 5,500 AFY by WY 2014-15. Groundwater pumping for treatment by the C. Marvin Brewer Desalter is also expected to increase from a baseline period average of about 500 AFY to an average of about 900 AFY in the future planning period. Since these planned desalter projects are expected to improve groundwater quality, they were designated as an implementation measure, as further discussed in Appendix J in the SNMP.
6	**Groundwater Reliability Improvement Program, Recycled Water Project A (GRIP A)** – This is a planned project in the Central Basin that would increase the use of recycled water, specifically a blend of AWT recycled water (10,000 AFY) and tertiary-treated recycled water (11,000 AFY) to completely replace imported water for recharge at the Montebello Forebay Spreading Grounds (MFSG) beginning WY 2017-18.
7	**GRIP Recycled Water Project B (GRIP B)** – This is a proposed project in the Central Basin that would increase the use of tertiary-treated recycled water (21,000 AFY) to completely replace imported water for recharge at the MFSG beginning WY 2014-15.
8	**Combined Projects/Scenarios** – A combination of Scenarios 2 (increased recycled water for irrigation at baseline period average S/N concentrations), 4, 5, 6 (GRIP A), and minor future changes (includes increased and decreased imported water for supply in the West Coast Basin and Central Basin, respectively, and increased stormwater capture).
9	**Combined Projects/Scenarios** – A combination of Scenarios 2 (increased recycled water for irrigation at baseline period average S/N concentrations), 4, 5, 7 (GRIP B), and minor future changes (includes increased and decreased imported water for supply in the West Coast Basin and Central Basin, respectively, and increased stormwater capture).
10	**Combined Projects/Scenarios** – A combination of Scenarios 3 (increased recycled water for irrigation at SMCLs/MCL), 4, 5, 6 (GRIP A), and minor future changes (includes increased and decreased imported water for supply in the West Coast Basin and Central Basin, respectively, and increased stormwater capture).
11	**Combined Projects/Scenarios** – A combination of Scenarios 3 (increased recycled water for irrigation at SMCLs/MCL), 4, 5, 7 (GRIP B), and minor future changes (includes increased and decreased imported water for supply in the West Coast Basin and Central Basin, respectively, and increased stormwater capture).

SNMP – Salt and Nutrient Management Plan
S/N – salt and nutrient
MCL – Maximum Contaminant Level
SMCL – Secondary Maximum Contaminant Level
Nitrate-N – nitrate as nitrogen
TDS – total dissolved solids
mg/L – milligrams per liter
CBWCB – Central Basin and West Coast Basin
AFY – acre-feet per year
WY – Water Year
GRIP – Groundwater Reliability Improvement Program
GRIP A – GRIP Recycled Water Project A
GRIP B – GRIP Recycled Water Project B
MFSG – Montebello Forebay Spreading Grounds

At this time, GRIP A and GRIP B alternatives are being further evaluated by WRD in terms of feasibility and cost and a Draft Environmental Impact Report (EIR) was issued for public review in March 2014 (accessed at: http://www.wrd.org/business/water-replenishment-grip.php). In the Draft EIR, GRIP A was identified as the "proposed project," while GRIP B was identified as an "alternative" to the "proposed project" (AECOM, 2014). As a result, it is anticipated that GRIP A likely would be the project to be implemented by WRD. However, this is subject to change until the Final EIR is prepared and certified by WRD.

Unchanged factors over the future planning period include subsurface basin inflows and outflows, groundwater pumping (except for the increase associated with the desalters), precipitation infiltration, mountain front recharge, and source water quality. These unchanged factors are represented as the average of the 10-year baseline period for each year of the future planning period.

The simulated conditions for the SNMP mixing model scenarios are summarized in **Table I-2**.

3 Groundwater Quality Trend Analysis

The Mann-Kendall statistical trend test is a nonparametric test that is commonly used to detect trends in a concentration time-series that compares the relative magnitudes of sample data. The Mann-Kendall test is particularly applicable to groundwater quality evaluations because the test is statistically robust and can be effectively applied to data sets with censored values (i.e., non-detects). **Attachment I-A** contains a more detailed description of the test. The Mann-Kendall test was used to assess whether TDS, chloride, and nitrate-N concentrations in WRD nested groundwater monitoring wells and production wells are increasing, decreasing, or showing no significant change. The trend analysis results, along with visual assessment of time-concentration plots for TDS, chloride, and nitrate-N in WRD nested monitoring wells (**Attachment I-B**), were used to help assess the dominant regional water quality trends in the basins and subareas to support the model calibration process discussed in Section 5.1.1.

The trend analysis was conducted using the entire period of record available for each well. Only those wells with 10 or more data points were evaluated to ensure that the requirements of the Mann-Kendall test were satisfied. The results of the trend analysis for each S/N are described below.

3.1 TDS Concentration Trends

Table I-3 presents the results of the Mann-Kendall test for TDS, chloride, and nitrate-N trends for each model layer, the combined layers within each subarea, the Central Basin, West Coast Basin, and entire CBWCB. Numbers in the table represent the number of wells within each trend category. Wells with unknown well completions are also shown in the table designated as "UNKNOWN." Figure 39 is a map illustrating the distribution of the trend results for TDS, chloride, and nitrate-N. TDS trend maps are shown along the left column of the figure, with Model Layer 1 on top and Model Layer 4 on the bottom. The TDS trend data are mixed with some wells increasing, some decreasing, and some showing no trend; however, the majority of wells in both basins are stable (i.e. no trend).

Table I-2 Summary of Simulated Conditions for the SNMP Mixing Model Scenarios

Scenario [a]	SIMULATED CONDITIONS										
	Average Baseline Precipitation and Mountain Front Infiltration, Pumping, Subsurface Flows	Irrigation with Recycled Water			WCBB/DGB/AGB		Desalters		MFSG		
		Average Baseline	Increased Volume and Baseline Average WQ	Increased Volume and MCL/SMCL WQ	Average Baseline	Increased Injection Volume with AWT	Average Baseline	Increased Pumping	Average Baseline	Tertiary and AWT Recycled Water	Tertiary Recycled Water
1. No Future Projects	✓	✓			✓		✓				
2. Increased Recycled Water for Irrigation (baseline period average WQ)	✓		✓		✓		✓		✓		
3. Increased Recycled Water for Irrigation (WQ at MCL/SMCLs)	✓			✓	✓		✓		✓		
4. Seawater Intrusion Barriers (increased injection volume and AWT RW)	✓	✓				✓	✓		✓		
5. Desalters – Increased Groundwater Pump & Treat (WCB only)	✓	✓			✓			✓	✓		
6. GRIP A (10K AFY AWT & 11K AFY tertiary-treated RW)	✓	✓			✓		✓			✓	
7. GRIP B (21K AFY tertiary-treated RW)	✓	✓			✓		✓				✓
8. Combined Scenarios (2 + 4 + 5 + 6 + Minor Future Changes)	✓		✓			✓		✓		✓	
9. Combined Scenarios (2 + 4 + 5 + 7 + Minor Future Changes)	✓		✓			✓		✓			✓
10. Combined Scenarios (3 + 4 + 5 + 6 + Minor Future Changes)	✓			✓		✓		✓		✓	
11. Combined Scenarios (3 + 4 + 5 + 7 + Minor Future Changes)	✓			✓		✓		✓			✓

a – Minor Future Changes, as referenced for all combined scenarios (Scenarios 8, 9, 10, and 11), include decreased imported water use for supply in the Central Basin, slightly increased imported water for supply in the West Coast Basin, and increased stormwater capture at the DGSG and other facilities

WQ – water quality for salt and nutrients
MCL – Primary Maximum Contaminant Level
SMCL – Secondary Maximum Contaminant Level
AWT – advanced water treatment
RW – recycled water
K – thousand
DGB – Dominguez Gap Seawater Intrusion Barrier
AGB – Alamitos Gap Seawater Intrusion Barrier
WCBB – West Coast Basin Seawater Intrusion Barrier
MFSG – Montebello Forebay Spreading Grounds
DGSG – Dominguez Gap Spreading Grounds
AFY – acre-feet per year
WCB – West Coast Basin
GRIP – Groundwater Reliability Improvement Program
GRIP A – Groundwater Reliability Improvement Program, Recycled Water Project A
GRIP B – Groundwater Reliability Improvement Program, Recycled Water Project B

(green box) baseline conditions
(peach box) future change

- Increasing Trend
- Decreasing Trend
- No Trend

a - Sum of Los Angeles Forebay, Montebello Forebay, Whittier Area, and Central Pressure Area

b - Sum of Central Basin and West Coast Basin

In the Central Basin, the Los Angeles Forebay has more wells with increasing TDS concentration trends (8) than decreasing trends (1), and four wells show no trends. While it is difficult to determine the reason for this trend pattern in the Los Angeles Forebay, examination of the trend data for two WRD multiple-completion monitoring wells shows higher TDS concentrations and more steeply increasing trends in the shallower wells compared with the deeper wells. These observations suggest loading from the surface as the reason for the increasing trends. It should be noted that TDS concentrations in the Montebello Forebay and the MFSG blended recharge water are well below concentrations in the Los Angeles Forebay. The Montebello Forebay provides subsurface recharge to the Los Angeles Forebay and managed aquifer recharge (MAR) in the Montebello Forebay are improving TDS groundwater quality overall in the Los Angeles Forebay.

In the Montebello Forebay, there are more wells with decreasing TDS concentration trends (21) than increasing trends (14), while the majority of wells (60) exhibit no trends. In the Whittier Area, most wells show no TDS concentration trends (4), with one well showing an increasing trend and no wells with decreasing trends. In the Central Basin Pressure Area, most wells (81) show no TDS concentration trends, while 35 wells show increasing trends and 21 wells show decreasing trends; so slightly more wells show increasing rather than deceasing trends. By summing the well numbers for all the subareas, the Central Basin as a whole has stable TDS concentrations, with most wells (149) showing no trends; in comparison, 61 wells show increasing trends and 43 wells show decreasing trends.

In the West Coast Basin, a greater number of wells (48) show no TDS concentration trends, while 30 wells show increasing trends and 16 wells show decreasing trends. While more wells have increasing rather than decreasing TDS concentrations, a closer examination of the location of the wells with increasing trends in Figure 39 indicates that many of the wells with increasing trends are likely influenced by the migration of saline plumes associated with historical seawater intrusion across the basin and not by current TDS loading. Given that the ambient background TDS concentrations are impacted by historical seawater intrusion, and ongoing mitigating measures such as the operation of the desalters and injection of high quality water at the seawater barriers for more than 40 years, ambient background TDS concentrations are declining overall in the West Coast Basin.

Overall for the CBWCB, TDS concentrations are predominantly stable, with most wells showing no TDS concentration trend (197), 91 wells showing increasing trends, and 59 wells showing decreasing trends (Table I-3).

3.2 Chloride Concentration Trends

Table I-3 and Figure 39 present the results of the Mann-Kendall test for water quality trends for chloride. Chloride trends are shown in the middle column of Figure 39, with Model Layer 1 on top and Model Layer 4 on the bottom. The trend data shows that chloride concentrations in most wells across each subarea are either stable or increasing, with fewer wells showing a decreasing trend.

In the Central Basin, the Los Angeles Forebay has more wells with increasing chloride concentration trends (7) than decreasing trends (3), and four wells show no trends. In the

Montebello Forebay, there are an equal number of wells (42) showing increasing and stable chloride concentration trends, with a smaller number of wells (11) showing decreasing trends. In the Whittier Area, most wells show no chloride concentration trends (4), with one well showing an increasing trend and no wells with decreasing trends. In the Central Basin Pressure Area, most wells (71) show no chloride concentration trends, while 62 wells show increasing trends, and 21 wells show decreasing trends. In the Central Basin as a whole, most wells show no chloride trends (121), while 112 wells show increasing trends, and 35 wells show decreasing trends. Increasing chloride trends are more prevalent at shallower depths (Model Layers 1, 2, and 3) compared with deeper depths (Model Layer 4). The reason for the significant number of wells with increasing chloride concentrations in the Central Basin is uncertain. It could be related to surface loading, but could also be related to dissolution of formation minerals in a system not at equilibrium.

In the West Coast Basin, a greater number of wells (42) show no chloride concentration trends, while 35 wells show increasing trends and 17 wells show decreasing trends. While there are more wells with increasing rather than decreasing chloride concentrations, a closer examination of the location of the wells with increasing trends on Figure 39 indicates that many of the wells with increasing trends are likely influenced by the migration of saline plumes associated with historical seawater intrusion across the basin and not by current chloride loading. Given that the saline plumes have been and continue to be actively remediated for more than 40 years through the injection of significant volumes of high quality water at the seawater barriers and the operation of the desalters, it is likely that ambient background chloride concentrations are declining overall in the West Coast Basin.

For the entire CBWCB, chloride concentrations are generally stable, with a greater number of wells (163) showing no trends; in comparison, 147 wells show increasing trends, and 52 wells show decreasing trends.

3.3 Nitrate Concentration Trends

Table I-3 and Figure 39 present the results of the Mann-Kendall test for water quality trends for nitrate. Nitrate trends are shown along the right column of the figure, with Model Layer 1 on top and Model Layer 4 on the bottom. The trend data generally show that nitrate concentrations are stable (i.e. no trend) in most wells in each subarea and basin, with a relatively small number of wells with decreasing nitrate trends outnumbering those with increasing trends.

In the Central Basin, most wells (5) in the Los Angeles Forebay show stable nitrate concentration trends, with 2 wells showing increasing trends and one well showing a decreasing trend. In the Montebello Forebay, most wells (42) show stable nitrate concentration trends, with a larger number of wells (25) showing decreasing trends compared with increasing trends (7). In the Whittier Area, most wells show no nitrate concentration trends (4), with one well showing a decreasing trend and no wells with increasing trends. In the Central Basin Pressure Area, most wells (61) show no nitrate concentration trends, while 6 wells show increasing trends and 5 wells show decreasing trends. In the Central Basin as a whole, nitrate concentrations are mainly stable, with most wells (112) showing no trends, 32 wells showing decreasing trends, and 15 wells showing increasing trends.

In the West Coast Basin, nitrate concentrations are also stable, with most wells (67) showing no trends, one well showing an increasing trend, and 3 wells showing decreasing trends.

Overall for the CBWCB, nitrate concentrations are primarily stable, with most wells (179) showing no trends, 16 wells showing increasing trends, and 35 wells showing decreasing trends.

4 Baseline and Future Planning Period Salt and Nutrient Balances

The S/N balances in the CBWCB consider the source water volumes of inflow and outflow and their associated TDS, chloride, and nitrate concentrations. The balances also consider any added TDS, chloride, and nitrate from use as well as other fate and transport processes, which can either increase or decrease S/N concentrations in groundwater. This section describes the methodology and data used to estimate key S/N loading and unloading factors and identify their individual and cumulative effects on groundwater quality in the CBWCB over the SNMP baseline period (WY 2000-01 to 2009-10) and future planning period (WY 2010-11 to 2024-25). The same loading factors developed and calibrated to baseline groundwater quality conditions were applied to the future planning period predictions.

Section 4.1 describes the general methodology used to develop the S/N balances. Sections 4.2 through 4.9 presents the S/N concentrations for individual source waters and key S/N inflows and outflows in the CBWCB. The overall S/N balances for the baseline period and future planning period are presented in Section 4.10.

4.1 Methodology to Develop Salt and Nutrient Balances

As discussed earlier, the SNMP mixing model was developed to simulate the effect of current S/N loading on groundwater quality in the CBWCB. The mixing model was designed to incorporate the existing volume of groundwater and mass of TDS, chloride, and nitrate in storage and track the annual change in groundwater storage and S/N mass for each model subarea and layer. S/N loading estimates for key inflows (including recharge at spreading grounds, seawater intrusion barrier injection, irrigation return flow, mountain front and precipitation recharge, and subsurface inflow) and outflows (including groundwater pumping and subsurface outflows) were estimated based on volumetric water budgets presented in Appendix H *Baseline and Future Water Balances*. The sensitivity of groundwater quality within each model subarea/layer to individual S/N loading factors was identified through numerous simulations, and selected S/N loading estimates and assumptions were refined to ensure a reasonable agreement between simulated and dominant patterns in observed groundwater quality conditions over the SNMP baseline period (WY 2000-01 through 2009-10). Loading assumptions developed based on the baseline period assessment were then applied to the future planning period S/N balances.

4.2 Surface Water/Stormwater Quality

Surface water quality (dry and wet weather) data are collected by the Los Angeles County Department of Public Works (LACDPW) at mass emissions (river) and tributary stations. In the CBWCB, river water quality data are also collected by the Council for Watershed Health (CWH) and the Sanitation Districts of Los Angeles County (SDLAC). The CWH collects annual river water quality data as part of its mission to monitor the health of the Los Angeles and San Gabriel River Watersheds. SDLAC collects samples in the rivers upstream and downstream of their recycled water discharge points. The WRD and SDLAC also collect samples from the MFSG intakes, specifically to the Rio Hondo Spreading Grounds and the San Gabriel River Spreading Grounds.

For S/N loading calculations, TDS, chloride, and nitrate data from several stations in the Study Area were assessed to determine the best water quality station to represent the surface water recharged at the MFSG and DGSG and mountain front recharge. LACDPW mass emission stations near and upgradient of the MFSG and DGSG include Station S10 (located just downstream of the DGSG) and Station S14 (located upstream of the San Gabriel River Spreading Grounds). The station locations are shown in Figure 64. SDLAC stations upstream of the Montebello Forebay include two along the San Gabriel River (R-10 and R-18) and one within the Rio Hondo (RD-1). Station R-18 is not a permitted receiving water station and was only used for a short period of time for a special study (Montebello Forebay Attenuation and Dilution Study [Kennedy/Jenks/Todd, 2008]). Average annual wet weather TDS, chloride, and nitrate data collected from these stations and the results of spreading grounds intake samples are summarized in **Table I-4**.

LACDPW Station S10 is the nearest station to the DGSG and is used to represent surface water quality recharged in these spreading grounds. For local surface water recharged at the MFSG, data from Stations S14, R-10, R-18, RD-1, and sampling results of the spreading grounds intake were assessed. Stations S14 and R-10 contain a portion of effluent from upgradient water reclamation plants (WRPs) even during wet weather and thus are not representative of only surface water/stormwater quality. The MFSG intake sampling results during storm events when recycled and imported water are not recharged provide the most representative water quality for local stormwater recharging the MFSG.

The other component of surface water recharged in the CBWCB is mountain front recharge. There are very little available data for surface water runoff in mountain front areas. The CWH has two Random Monitoring Stations (SGLR00190 and SGLR030) with one sampling event each for electrical conductivity and nitrate-N, but no data for chloride (see Figure 64). In its sampling design, CWH integrates various types of surface water monitoring sites including both probabilistic randomized sites (Random Monitoring Stations) and targeted sampling at fixed sites (Fixed Monitoring Stations). Random Monitoring Stations are monitored less frequently than Fixed Monitoring Stations. TDS concentrations can be estimated from electrical conductivity values. The samples showed very different water quality. Because surface water quality can vary considerably based on the type of event sampled (i.e. first flush, dry flow, or wet season flow), the two sampling points are not adequate to estimate annual

mountain front recharge over the 10-year baseline period. As a result, MFSG intake sample results were used to represent mountain front recharge water quality.

4.3 Imported Water Quality

Imported water is used for potable supply and replenishment in the CBWCB. Imported water is provided by the Metropolitan Water District of Southern California (MWD), City of Los Angeles Department of Water and Power (LADWP), City of Whittier, Suburban Water Company, California Domestic Water Company, and San Gabriel Valley Water Company. Locations of MWD and LADWP imported water storage and treatment facilities are shown in Figure 65.

MWD imports water from the Colorado River (CR) and State Water Project (SWP) and supplies untreated water to the MFSG and treated water for potable supply and for injection at the seawater intrusion barriers. The S/N water quality for these two sources is different and thus, it was necessary to estimate the relative percentages of each water source delivered to the recharge projects and used for drinking water supply and irrigation in order to characterize the recharge water quality. Untreated water is delivered to the MFSG from MWD Meters CB-28 and CB-48 located in the Santa Ana Valley Basin and San Gabriel Basin, respectively. The water is transported via surface water to the MFSG and San Gabriel River instream recharge facilities. Water from Meter CB-28 originates from the Lake Silverwood and Lake Mathews reservoirs. Lake Silverwood is part of the SWP and is owned by the State of California and operated by the DWR. Lake Mathews is an MWD-owned and operated reservoir. Lake Silverwood contains 100% SWP water, while Lake Mathews contains 100% CR water. The mix of these two source waters delivered to Meter CB-28 is highly variable. Water from Meter CB-48 originates entirely from Lake Silverwood and is thus, 100% SWP water. MWD has estimated the relative percentage of CR and SWP water delivered to the MFSG each year during the SNMP baseline period. **Table I-5** shows the TDS, chloride, and nitrate water quality during the SNMP baseline period for untreated CR and SWP water and the estimated blended water quality delivered to the MFSG. Note that recharge water in the Montebello Forebay includes recycled water and local water in addition to untreated imported water.

Treated water from MWD's Jensen and Diemer Water Treatment Plants (WTPs) is delivered to the Dominguez Gap Seawater Intrusion Barrier (DGB) and Alamitos Gap Seawater Intrusion Barrier (AGB) for injection. The Jensen WTP treats and delivers 100% SWP water. The Diemer WTP treats and delivers a highly variable blend of SWP and CR water. Water from MWD's Jensen, Diemer, and Weymouth WTPs is delivered to the CBWCB for potable supply. The Weymouth WTP also treats and delivers a highly variable blend of SWP and CR water. **Table I-6** shows the annual average TDS, chloride, and nitrate-N concentrations in the effluent from MWD's Jensen, Diemer, and Weymouth WTPs.

The LADWP imports and treats water from the Owens River/Mono Basin. The LADWP also treats some raw SWP water delivered by MWD to LADWP's Los Angeles Aqueduct Treatment Plant. This water is delivered to both the Central Basin and West Coast Basin for potable supply. **Table I-7** provides the annual average TDS, chloride, and nitrate-N concentrations in LADWP-imported water during the baseline period.

The City of Whittier, Suburban Water Company, California Domestic Water Company, and San Gabriel Valley Water Company import groundwater extracted from the San Gabriel Basin for water supply in the Study Area. In addition, in WYs 2000-01 and 2002-03, a small amount of groundwater extracted from the Whittier Narrows area in the San Gabriel Basin was also delivered to the Montebello Forebay for replenishment. **Table I-8** presents the annual average TDS, chloride, and nitrate-N concentrations in these water sources during the baseline period.

4.4 Recycled Water Quality

In the CBWCB, recycled water has many uses, including groundwater recharge, urban landscape irrigation, agricultural irrigation, industrial and commercial process water, recreational facilities, and wildlife habitat maintenance. Treatment plants in the CBWCB that produce this recycled

water are owned and operated by the SDLAC, West Basin Municipal Water District (WBMWD), City of Los Angeles, and WRD. Locations of wastewater treatment plants are shown in Figure 66.

Relevant to the S/N balances is recycled water used for replenishment operations and irrigation in the Study Area, as other recycled water uses do not recharge the groundwater basins. Recycled water from the Pomona, San Jose Creek, and Whittier Narrows WRPs operated by the SDLAC is recharged in the Montebello Forebay. Recycled water from SDLAC's Long Beach, Los Coyotes, and San Jose Creek WRPs is used for irrigation and commercial/industrial applications in the Central Basin. The WRPs provide primary treatment, nitrification/denitrification (NdN) activated sludge biological treatment, granular media filtration, disinfection, and dechlorination.

Advanced treated recycled water produced by the Leo J. Vander Lans Advanced Water Treatment Facility (Vander Lans AWTF), owned by WRD, is injected at the AGB into the Central Basin and adjacent Orange County Basin. Advanced water treatment processes at the Vander Lans AWTF historically consisted of microfiltration (MF), reverse osmosis (RO), and ultraviolet irradiation (UV). During WY 2014-15, when the Vander Lans AWTF was expanded to produce from 3,360 AFY to 8,960 AFY of AWT recycled water, the treatment train was modified to also receive advanced oxidation process (AOP) through the addition of peroxide.

Advanced treated recycled water produced by the Edward C. Little Water Reclamation Facility (WRF), owned by the WBMWD, is injected at the West Coast Basin Seawater Intrusion Barrier (WCBB). Tertiary-treated recycled water produced by the Edward C. Little WRF is used for irrigation in the West Coast Basin. Treatment processes at the Edward C. Little WRF consists of MF, RO, AOP, and chemical stabilization. In 2013, the Edward C. Little WRF was expanded to produce from 14,000 AFY to 19,600 AFY of recycled water and the treatment train now includes ozonation (O_3).

Advanced treated recycled water from the Terminal Island Water Reclamation Plant/Advanced Water Purification Facility (TIWRP), owned by the City of Los Angeles, is injected at the DGB. A small amount of tertiary-treated recycled water produced by the TIWRP is used for local irrigation at the treatment facility. The TIWRP provides tertiary treatment, MF, RO, and chlorination and the facility capacity is 5,600 AFY. The TIWRP is currently undergoing expansion activities and by WY 2018-19, the TIWRP is expected to produce 11,200 AFY of AWT recycled water and treatment will also include AOP and chemical stabilization.

Annual average TDS, chloride, and nitrate-N concentrations for each recycled water source used for irrigation and/or replenishment in the Study Area are provided in **Table I-9**. TDS, chloride, and nitrate-N were not required monitoring parameters for the AWT recycled water produced by the TIWRP during the baseline period. In order to estimate the future planning period blend water quality for the DGB, S/N concentrations in the AWT recycled water is needed. In order to establish S/N concentrations for the AWT recycled water used for the DGB, a special sampling event was conducted at the TIWRP in July and August 2013 for TDS and chloride. The average of 2011 nitrate-N data for the TIWRP and the average of the special sampling conducted for TDS and chloride are provided at the bottom of Table I-9 and was used to calculate the future planning period S/N concentrations for blended water injected at the DGB.

Water conservation has the potential to impact the quality of recycled water by increasing salt concentrations due to reduced influent flows. SDLAC evaluated its WRPs in the CBWCB in terms of flow reductions and changes in TDS and chloride.[1] While wastewater flows have declined since 1998, TDS concentrations have remained steady and do not appear to be impacted by water conservation. However, chloride trends are a bit different. For the six

f - Used at the Alamitos Gap Barrier; data provided by WRD; the LVL AWTF came online in 2006

facilities that make up SDLAC's Joint Outfall System (including the WRPs that provide recycled water in Central Basin), chloride has increased at the Joint Water Pollution Control Plant, La Cañada WRP, and Whittier Narrows WRP. SDLAC has observed a slight increase at the Pomona WRP and San Jose Creek East WRP, but since chloride concentrations appear to be cyclical at these plants, this trend is not definitive. Chloride levels are staying steady or dropping at the Long Beach, Los Coyotes, and San Jose Creek West WRPs, although this trend may be influenced by chloride industrial dischargers shutting down or being rerouted to other plants. Assessment of the WBMWD's Edward C. Little WRF tertiary-treated recycled water quality presented in Table I-9 shows a significant increase in both TDS and chloride beginning in 2005-06. Based on these findings, tertiary-treated recycled water used for irrigation was simulated at both the average of baseline period concentrations and at higher concentrations in the future planning period as described Section 2.3 *Scenarios Simulated to Estimate Future Groundwater Quality.*

4.5 Groundwater Quality

Groundwater in the CBWCB is used for water supply. Groundwater recharges the basins through deep percolation of groundwater used for irrigation. The CBWCB also receives subsurface inflows from adjacent groundwater basins and the ocean. A small amount of groundwater leaves the CBWCB as subsurface outflow. Groundwater primarily leaves the basins through well pumping.

Irrigation water return flow is a mix of groundwater, imported water, and recycled water and is discussed in the Section 4.8 *Irrigation Return Flow Water Quality*. In addition to irrigation return flows, groundwater from adjacent basins and the ocean flows into the Study Area as subsurface inflow. **Table I-10** provides the TDS, chloride, and nitrate-N concentrations in the groundwater entering the Study Area as subsurface inflow. Groundwater can leave the CBWCB as subsurface outflow. Calculation of the average TDS, chloride, and nitrate-N concentrations in CBWCB groundwater is discussed in Appendix G *Hydrogeologic Conceptual Model and Existing Salt and Nutrient Groundwater Quality.* **Table I-11** presents the TDS, chloride, and nitrate-N groundwater quality of each subarea/layer in the Study Area. For each basin and for the Central Basin Pressure Area, two average concentrations were calculated: one average includes the coastal areas (i.e. seaward side of the seawater intrusion barriers) and the other average excludes these coastal areas (see Figure 2). Due to the significant influence of the WCBB-inland saline plume (shown in Figure 2) on the average groundwater quality in West Coast Basin, the average groundwater quality in the West Coast Basin also was calculated without the saline plume area and coastal areas.

As shown in Table I-11 and Figure 40 and discussed in Appendix G *Hydrogeologic Conceptual Model and Existing Salt and Nutrient Groundwater Quality,* average TDS, chloride, and nitrate concentrations in the Central Basin are below BPOs, and assimilative capacity is available. Due to historical seawater intrusion in the West Coast Basin, average TDS and chloride concentrations exceed Basin-Specific Basin Plan Objectives (BSBPOs) when the WCBB-inland saline plume area is included and, as a result, there is no assimilative capacity. Average nitrate concentrations in the West Coast Basin are well below the BPO and assimilative capacity is available for nitrate. As shown in Table I-11 and Figure 40, when the saline plume and coastal

TDS - total dissolved solids
Cl - chloride
NO_3-N - nitrate as nitrogen
OCWD - Orange County Water District
CDPH - California Department of Public Health
mg/L - milligrams per liter

a - Data from CDPH (http://www.cdph.ca.gov/certlic/drinkingwater/Documents/Monitoringschedule/DistrictReports-Monitoring%20Page/CentralL.A.District16.pdf)
b - Data from Upper Los Angeles River Area Watermaster Annual Reports 2001 to 2011, Well Pollock No. 6
c - From LACDPW Well 2947LM; well used by San Gabriel River Watermaster to represent Whittier Narrows water quality
d - Data provided by OCWD; values in table represent overall average concentrations applied; different concentrations were applied for each model layer based on available nested well data; concentrations in each layer were kept constant for the 10 year baseline period due to limited geographic coverage across the County boundary and complications of variable inflow and outflow across the boundary over the 10 year baseline period
e - Average concentration in areas seaward of barriers
f - Because limited data were available, the average of 10 wells and 10 samples taken between 1994 and 2012 is used to represent water quality in all years
g - Because limited data were available, the average of 4 wells and 4 samples taken between 2011 and 2012 is used to represent water quality in all years
h - Data interpolated for missing years

TDS - total dissolved solids
Cl - chloride
NO_3-N - nitrate as nitrogen
NA - not applicable; no Model Layer 1 in these areas
Averages based on groundwater concentration contour maps; average of all layers is a weighted average based on area and aquifer thickness
Negative numbers indicate there is no available assimilative capacity
BPO/BSBPO - Basin Plan Objective or Basin Specific Basin Plan Objective
(shaded orange) - Average concentration indicated exceeds BPO
(shaded gray) - Model Layer 1 not included; typically unsaturated within the Los Angeles Forebay and of very limited extent Whittier Area (see explanation in Section 2.5.3 in Appendix G *Hydrogeologic Conceptual Model and Existing Salt and Nutrient Groundwater Quality*)
a - Includes both Central Basin and West Coast Basin
b - Elevated TDS and chloride concentrations in the Whittier Area are likely naturally occurring as discussed in Section 3.5.3.2 in Appendix G *Hydrogeologic Conceptual Model and Existing Salt and Nutrient Groundwater Quality*

areas are removed from the West Coast Basin average calculations, the West Coast Basin does have available assimilative capacity for TDS, chloride, and nitrate. If seawater-impacted areas in the vicinity of the DGB were also removed from these average concentrations, there would be more available assimilative capacity. This calculation was performed only for existing conditions, i.e. baseline period, because it is too technically complex to simulate the West Coast Basin without the saline plume in the groundwater model, which is necessary for the mixing model analysis.

The Central Basin (excluding the coastal area) average groundwater quality provided in Table I-11 was used to represent the quality of groundwater removed through pumping in the Central Basin in WY 2000-01 in the mixing model. This is reasonable because production wells are generally evenly distributed across the basin. The mixing model used these initial values for the groundwater pumped from the basin and adjusted them for subsequent years based on other S/N inflows and outflows. A slightly different approach was required for estimating TDS and chloride removed through pumping in the West Coast Basin due to the high basin-wide average TDS and chloride concentrations as a result of the saline plume located inland of the WCBB. If the same approach used in the Central Basin were applied to the West Coast Basin, the high basin-wide average TDS and chloride concentrations would result in an overestimation of the TDS and chloride removed through pumping. Because pumping wells in the West Coast Basin are clustered and not well distributed and very few wells are located near or within the saline plume, average S/N concentrations in pumped groundwater in the West Coast Basin were calculated using individual active well pumping volumes and quality (volume-weighted average of pumping wells), not the basin-wide averages developed from concentration contour maps (discussed in Appendix G *Hydrogeologic Conceptual Model and Existing Salt and Nutrient Groundwater Quality* and presented in Table I-11).

Since nitrate concentrations do not vary across the West Coast Basin, the same method used in the Central Basin was used to calculate nitrate concentrations in groundwater pumped from the West Coast Basin. Accordingly, the average nitrate-N concentrations presented in Table I-11 were used to represent WY 2000-01 pumped groundwater quality and the SNMP mixing model was used to adjust the concentrations for subsequent years based on nitrate inflows and outflows. The estimated groundwater quality of S/Ns removed from the West Coast Basin by extraction is presented in **Table I-12**.

The C. Marvin Brewer (Brewer) Desalter and Robert W. Goldsworthy (Goldsworthy) Desalter treat brackish groundwater pumped from the WCBB-inland saline plume. The desalters help to remediate the trapped inland saline plume and the treated water is used for potable supply. Groundwater extraction for the desalters is projected to increase in the future planning period as described in Appendix H *Baseline and Future Water Balances.* The median concentrations of TDS and chloride in the raw groundwater pumped for the desalters from 2007 to 2012 is presented in **Table I-13**. Since nitrate concentrations do not vary across the West Coast Basin, the average nitrate-N concentrations presented in Table I-11 were used to represent WY 2000-01 desalter groundwater quality and the SNMP mixing model was used to adjust the concentrations for subsequent years based on nitrate inflows and outflows.

Table I-12 Average TDS, Chloride, and Nitrate-N Concentrations in Groundwater Pumped from the West Coast Basin

WATER YEAR	EXTRACTED GROUNDWATER QUALITY IN WEST COAST BASIN [a] (volume-weighted average in mg/L)

Cl - chloride

NO_3-N - nitrate as nitrogen

a - Data from WRD water quality database; the median concentration from 2007-2012 was applied directly for wells with TDS and chloride data; one calculated value was used for all 10 years of the baseline period because the well water quality data are insufficient to support calculation of different annual averages

b - Nitrate value based on West Coast Basin (no coastal areas) average from Table 5; subsequent year nitrate concentrations estimated with mixing model

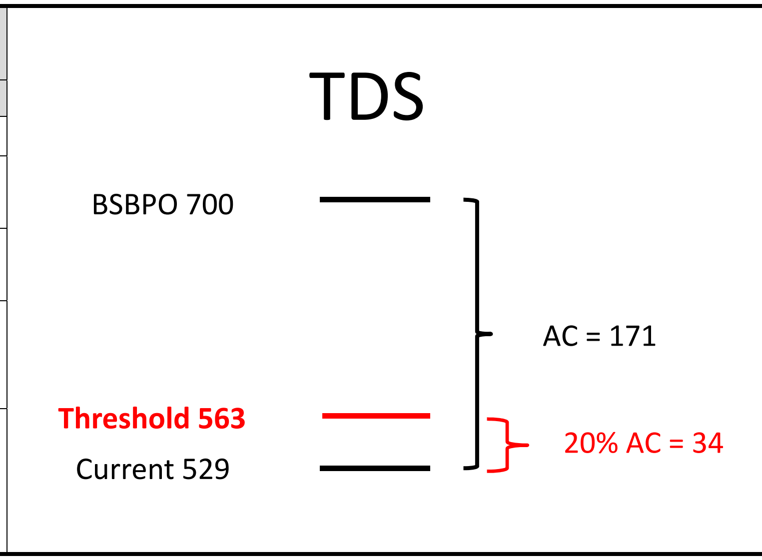
4.6 Assimilative Capacity Threshold

There are multiple recycled water projects in operation throughout the CBWCB. Ongoing major recycled water projects in the Central Basin include the MFSG, AGB, and irrigation with recycled water. In the West Coast Basin, existing major recycled water projects include the WCBB, DGB, and irrigation with recycled water. In accordance with the State Water Resources Control Board's (SWRCB) Recycled Water Policy, single recycled water projects utilizing less than 10% and multiple projects utilizing less than 20% of the available assimilative capacity in a basin/sub-basin need only conduct an anti-degradation analysis verifying the use of the assimilative capacity. Accordingly, single and multiple recycled water projects proposed in the CBWCB were assessed in terms of 10% and 20% of the existing available assimilative capacity, respectively. The 20% assimilative capacity threshold is provided in Table I-11.

Table I-14 provides an example of how the 20% assimilative capacity threshold was calculated for TDS groundwater quality in the Central Basin. The existing average TDS concentration in the basin was subtracted from the BSBPO to calculate the available assimilative capacity. 20% of the calculated available assimilative capacity was then added to the average TDS concentration to determine the assimilative capacity threshold. Similar steps were used to calculate the 20% and 10% assimilative capacity threshold for each S/N for each basin.

Table I-14 Calculation of Assimilative Capacity Threshold

	Central Basin (no coastal area)		
	TDS	**Cl**	**NO_3-N**
BPO/BSBPO	700	150	10.0
Average Concentration	529	67	0.28
Assimilative Capacity	171	83	9.72
20% Assimilative Capacity	**34**	17	1.94
20% Assimilative Capacity Threshold	**563**	84	2.22



All values in milligrams per liter
TDS – total dissolved solids
Cl – chloride
NO_3-N – nitrate as nitrogen
BPO/BSBPO – Basin Plan Objective/Basin-Specific Basin Plan Objective
AC – assimilative capacity
Coastal area – Seaward side of the seawater intrusion barrier

4.7 Montebello Forebay Spreading Water Quality

Water recharged in the Montebello Forebay includes untreated imported water (from CR and SWP), recycled water, and local water/stormwater. These source waters and their volumes recharged at the MFSG between WY 2000-01 through 2009-10 are described in Appendix H *Baseline and Future Water Balances*. The relative percentages of each source water and its quality (volume-weighted average) were used to estimate the S/N inflow from the managed aquifer recharge in the Montebello Forebay. **Table I-15** shows the estimated baseline and future planning period annual average S/N concentrations in water recharged at the MFSG.

Table I-15 Annual Average TDS, Chloride, and Nitrate-N Concentrations in Water Recharged at the MFSG

Water Year	PROJECTED QUALITY OF BLENDED RECHARGE WATER AT MFSG [a] (volume-weighted average in mg/L)					
	SCENARIO 6 - GRIP A 11,000 AFY tertiary & 10,000 AFY AWT Recycled Water [b]			SCENARIO 7 - GRIP B 21,000 AFY Tertiary Recycled Water

2022-23	415	87	2.67	460	98	2.85
2023-24	415	87	2.67	460	98	2.85
2024-25	415	87	2.67	460	98	2.85
Average 2011 to 2025	422	89	2.60	450	95	2.75

TDS - total dissolved solids
Cl - chloride
NO_3-N - nitrate as nitrogen
MFSG - Montebello Forebay Spreading Grounds
GRIP - Groundwater Reliability Improvement Program
GRIP A - GRIP Recycled Water Project A
AWT - advanced water treatment
AFY - acre-feet per year
AWTF - advanced water treatment facility
mg/L - milligrams per liter
GRIP B - GRIP Recycled Water Project B

a - Concentrations calculated based on spreading grounds source volumes and source water concentrations (volume-weighted average)

b - AWT recycled water quality represented by average baseline concentrations from WRDs Leo J. Vander Lans AWTF

Table I-15 shows the projected quality of the recharge water for both GRIP A and GRIP B (Scenarios 6 and 7, respectively, simulated by the SNMP mixing model, as discussed in Section 2.3). The projected water quality is a volume-weighted average of the source waters. The baseline period average water quality is used to represent future source water quality for imported water, stormwater, and tertiary-treated recycled water. For the AWT recycled water, the average baseline period water quality from WRD's Vander Lans AWTF was used for the volume-weighted averages for GRIP A. The projected TDS, chloride, and nitrate concentrations in the MFSG recharge water are higher for the 100% tertiary-treated recycled water scenario (GRIP B) compared with baseline conditions. The AWT/tertiary-treated recycled water blend (GRIP A) has similar average TDS, chloride, and nitrate concentrations to baseline conditions. The projected recharge water quality is well below BPOs for TDS, chloride, and nitrate for both GRIP A and GRIP B.

4.8 Seawater Barrier Injection Water Quality

The seawater intrusion barriers currently receive treated MWD imported water and AWT recycled water. These source waters and relative volumes are described in Appendix H *Baseline and Future Water Balances*. The delivered water quality (annual S/N concentrations) is reported in **Table I-16** for each seawater intrusion barrier for the baseline period. During the future planning period, AWT recycled water will replace imported water at all three barriers and overall injection volumes are projected to increase. AWT recycled water is projected to fully replace imported water at the AGB in WY 2014-15, at the WCBB in WY 2013-14, and at the DGB in WY 2018-19. Table I-16 shows the projected S/N concentrations in the recharge water for each barrier. The projected water quality is a volume-weighted average of the source waters. The baseline period average water quality is used to represent future source water quality for imported water and AWT recycled water at the WCBB and AGB.

For the DGB, AWT recycled water from City of Los Angeles' TIWRP is not normally tested for TDS and chloride. To provide a basis for the future blending calculations, samples of the AWT recycled water were analyzed in July and August 2013 and the average of these samples was used to represent average TDS and chloride concentrations in the AWT recycled water in the future planning period. For nitrate, 2011 AWT recycled water sampling results were used to represent the average for blending.

4.9 Irrigation Return Flow Water Quality

Water used for irrigation in the CBWCB includes imported water, groundwater, and recycled water. In order to determine the average S/N concentrations in irrigation return flows that percolate to groundwater, the relative volumes of each source water (described in Appendix H *Baseline and Future Water Balances*) were multiplied by their S/N concentrations to determine the irrigation water quality.

In addition to the S/Ns in the source water, S/Ns can become concentrated or attenuate due to evapotranspiration, removal by plant uptake, attenuation processes, or through fertilizer use. Nutrient plant uptake is the process by which plants absorb nutrients from applied water and surrounding soil.

Table I-16 Annual Average TDS, Chloride, and Nitrate-N Concentrations for Water Injected at Seawater Intrusion Barriers

LADWP - Los Angeles Department of Water and Power
AWT - advanced water treatment

a - Data for baseline period provided by WRD; future planning period water quality calculated as a volume weighted average of source water volumes and average baseline period water quality

b - Data for baseline period provided by WBMWD; future planning period water quality calculated as a volume weighted average of source water volumes and average baseline period water quality

c - Water quality data for baseline period delivered water provided by Michael Hanson, LADWP; no data available for NO_3 for DGB for 2005-2006 so 2006-07 data used; future planning period water quality calculated as a volume weighted average of source water volumes and TDS and chloride sampling from July/August 2013 provided by Seung Tag Oh, LADWP, and nitrate data from LADWP 2011 Harbor Water Recycling/DGB Project 2011 Annual Report (February 2012)

There are limited available data to derive the nitrate load from urban fertilizer use. A recent UC Davis study of nitrate loading in five California counties provides a method for estimating this load. The upper limit of leaching from fertilizer applications on golf courses and other urban turf was estimated at 8.9 pounds of nitrogen per acre (UC Davis, 2012). This assumes an application rate of 45 pounds of nitrogen per acre per year, of which 36 pounds is lost before reaching groundwater. Nitrogen losses are due to plant uptake and volatilization and denitrification processes, which account for the loss of 90% of the applied nitrogen. This correlates to 5.5 mg/L of added nitrate-N to the volume-weighted source water concentrations.

Nitrate concentrations percolating to groundwater were adjusted based on the mixing model calibration process as discussed in Section 5.1.1 *Mixing Model Baseline Period Calibration.* To match the dominant trends in actual observed groundwater quality, an attenuation factor of 0.1 was applied. Evapotranspiration (ET) of the irrigation water results in salts and nitrate becoming more concentrated when it reaches groundwater. It is assumed that only 3.6% of the applied irrigation percolates to groundwater, as described in Appendix H *Baseline and Future Water Balances*. This represents a potential 36-fold increase in the concentration of salt. A 9-fold increase in TDS and chloride concentration (nitrate was accounted for in leaching values calculated in the 2012 UC Davis study) was assumed to account for ET concentration. The potential 36-fold increase was reduced to a 9-fold increase during the calibration process, as discussed in Section 5.1.1 *Mixing Model Baseline Period Calibration*, in order for the simulated salt concentration to more closely match the dominant actual observed groundwater quality trends. It is assumed that 12% of the Study Area is irrigated. This is based on the UC Davis study (2012), which estimated between 12% and 23% of irrigated turf in urban areas. The lower end of the range was selected based on existing conservation efforts and water rationing implemented in the Study Area during severe droughts, resulting in the replacement of lawns with lower water-use landscaping. **Table I-17** presents the TDS, chloride, and nitrate-N concentrations in raw irrigation water (i.e. consisting of treated imported water, groundwater, and recycled water) and irrigation return flows, assuming the effects on water quality due to fertilizer use, ET, and nitrogen attenuation.

4.10 Precipitation Percolation Water Quality

Precipitation recharges the groundwater basins through deep percolation. Generally, precipitation is low in S/Ns. Precipitation can pick up or leach salts and nutrients in the surface soils, vadose zone, and aquifer (mineral dissolution). Because precipitation water quality is so low with respect to TDS and chloride, it was assumed that precipitation will react with surface soils and subsurface media to leach these salts. Thus, TDS and chloride loading was adjusted through the SNMP mixing model calibration process, as discussed in Section 2.1 *Mixing Model Calibration*.

The process by which airborne pollutants are deposited to the earth is known as dry deposition. Nitrogen is one of the pollutants commonly associated with dry deposition. For the SNMP analysis, nitrogen leaching from dry deposition is assumed to be negligible. This is consistent with the UC Davis Study (2012), which assumed nitrogen in urbanized areas runs off with stormwater flows or is removed by nitrogen-fixing processes in turf areas. **Table I-18** provides the water quality for raw precipitation and the adjusted percolation water quality for the

Table I-17 Annual Average TDS, Chloride, and Nitrate-N Concentrations in Raw Irrigation Water and Return Flows

TDS - total dissolved solids
Cl - chloride
NO_3-N - nitrate as nitrogen
MCL - primary maximum contaminant level
ET - evapotranspiration
WRPs - water reclamation plants
WRF - water reclamation facility
SMCL - secondary maximum contaminant level
SDLAC - Sanitation Districts of Los Angeles County
WBMWD - West Basin Municipal Water District
mg/L - milligrams per liter

See Section 4.8 of Appendix I *Baseline and Future Salt and Nutrient Groundwater Quality* for additional discussion of irrigation return flow loading assumptions

a - TDS and chloride concentrations increased 9 fold due to ET based on initial potential 30 fold increase adjusted downward based on mixing model calibration

b - Fertilizer application rate - net loading to groundwater is 8.9 pounds of nitrogen per acre based on UC Davis (2012 study) application rate of 45 pounds/acre, 36 pounds lost prior to leaching. 5.5 mg/L added; nitrate attenuated 90% based on mixing model calibration

c - Baseline recycled water quality is a volume-weighted blend of effluent from SDLAC's San Jose Creek, Los Coyotes, and Long Beach WRPs in Central Basin and effluent from WBMWD's Edward C. Little WRF in the West Coast Basin; for future planning period average of baseline period used for volume-weighted averages

d - Baseline imported water quality is a volume-weighted mix of treated imported water sources; for future planning period, baseline average used for volume-weighted average

e - Baseline groundwater quality used in volume-weighted averages is basin average for Central Basin and basin average excluding refinery industrial wells for the West Coast Basin; for future planning period, baseline average used for volume-weighted average

TDS - total dissolved solids
Cl - chloride
EC - electrical conductivity
NO_3-N - nitrate as nitrogen

a - Data from USEPA CASTNET; Station Converse (CON186); San Bernardino County; TDS calculated from EC

b - zero values indicate non detects; no detection limits provided

c - TDS and chloride concentrations increased through mineral

d - This is the change in precipitation recharge between the baseline period average and WY 2025 baseline period. The average of the baseline period was used for the precipitation return flows for the future planning period.

4.11 Overall Salt and Nutrient Balances

TDS, chloride, and nitrate balances were developed for the 10-year baseline period (WY 2000-01 to 2009-10) and the future planning period (WY 2010-11 to 2024-25) based on the water quality described above. Salt and nutrient balances for various scenarios, as described in Section 2.3 *Scenarios Simulated to Estimate Future Groundwater Quality,* were estimated for the future planning period from WY 2010-11 to 2024-25. TDS, chloride, and nitrate balances are the basis for the mixing model water quality predictions.

Tables illustrating the TDS, chloride, and nitrate-N balance values for the Central Basin and West Coast Basin for the baseline period and for Scenarios 1, 8, 9, 10, and 11 of the future planning period are presented in **Attachment I-C**. Figures 41 through 58 present the S/N balances graphically. The Central Basin S/N balance is shown on the top of each figure, and the West Coast Basin S/N balance is shown on the bottom of each figure. A discussion of key findings is presented below.

4.11.1 TDS

4.11.1.1 Baseline Period

Figure 41 shows the TDS mass balances for the baseline period (WY 2000-01 to 2009-10) for the Central Basin and West Coast Basin. As shown in Figure 41, recharge at the MFSG is the largest TDS load to the Central Basin, followed by irrigation return flows and subsurface inflow. Deep percolation of precipitation, AGB injection, and mountain front recharge are minor TDS loading sources. Minor TDS loading associated with recharge at the DGSG in the Central Basin is included with the MFSG loading shown in Figure 41. In the Central Basin, groundwater pumping is the major TDS outflow, along with a small amount of subsurface outflow to the West Coast Basin. Annual changes in TDS mass vary considerably from year to year with an overall increase in cumulative TDS mass of about 11,900 tons in groundwater in the Central Basin over the baseline period. This mass change equates to an increase of 2.6 mg/L of TDS in groundwater over 10 years.

In the West Coast Basin, subsurface inflow from the ocean and adjacent basins is the largest TDS source, followed by irrigation return flows and injection at the seawater intrusion barriers. Smaller components of TDS loading include deep percolation of precipitation, mountain front recharge, and recharge at the DGSG. Groundwater pumping is the only TDS outflow as there is no subsurface outflow. Annual changes in TDS mass vary from year to year but are consistently negative, thereby indicating a net decrease in TDS mass in groundwater. The cumulative change in TDS mass in the West Coast Basin over the baseline period is a decrease of about 78,500 tons, equivalent to a decrease of 15.2 mg/L of TDS in groundwater over the 10 years.

4.11.1.2 Future Planning Period

Figures 42 through 46 illustrate the TDS mass balances for the future planning period (WY 2010-11 to 2024-25) for Scenario 1 (the No Future Projects Scenario) and Scenarios 8 through 11 (various combinations of proposed projects), respectively. For Scenarios 1 and 8 through 11, the MFSG recharge is the largest TDS loading source in the Central Basin followed by subsurface inflow and irrigation return flows. Precipitation infiltration, mountain front recharge, and AGB injection are minor TDS loading sources. Groundwater pumping is the major TDS outflow along with a small amount of subsurface outflow to the West Coast Basin. TDS loading is highest under scenarios that include GRIP B (Scenarios 9 and 11), with Scenario 11 having a higher TDS load than Scenario 9 due to the difference in simulated recycled water TDS concentrations. Under the No Future Projects Scenario (Scenario 1), the cumulative (WY 2010-11 to 2024-25) TDS mass increase in groundwater is about 19,200 tons, while the TDS mass increase for Scenarios 8 through 11 ranges from 28,300 to 103,800 tons. Increases in TDS mass do not necessarily correlate to increases in average groundwater TDS concentrations, as the volume change associated with TDS mass change must also be considered. For example, while cumulative TDS mass increases under Scenarios 8 through 10 are larger than for the No Future Projects Scenario, projected average TDS concentrations in the Central Basin are lower for Scenarios 8 through 10. This occurs because the water budget indicates a net positive storage change under Scenarios 8 through 10 and a net negative storage change under the No Future Projects Scenario. Only under Scenario 11 does the effect of combined projects result in a larger positive TDS mass increase and higher average groundwater TDS concentrations in the Central Basin compared to the No Future Projects Scenario.

For the No Future Projects Scenario and Scenarios 8 through 11 in the West Coast Basin (Figures 42 through 46), subsurface inflow followed by irrigation return flows and injection at the seawater barriers are the largest TDS sources. Precipitation infiltration, mountain front recharge, and recharge at the DGSG are minor TDS loading sources. Groundwater pumping is the only TDS outflow. TDS loading is less under Scenarios 8 through 11 compared with the No Future Projects Scenario as a result of two factors: 1) reduced TDS loading from increased AWT recycled water used at the seawater barriers under Scenarios 8 through 11, and 2) increased removal of TDS mass from groundwater due to increased desalter well pumping under Scenarios 8 through 11. Under the No Future Projects Scenario, the cumulative (WY 2010-11 to 2024-25) TDS mass decrease in groundwater is about -22,200 tons, equating to a decrease of -23.0 mg/L of TDS over the 15 years. In comparison, under Scenarios 8 through 11, the cumulative (WY 2010-11 to 2024-25) TDS mass decrease in groundwater ranges from 348,400 to 352,900 tons, equating to a groundwater TDS concentration decrease of 56.7 to 57.4 mg/L over the 15 years.

4.11.2 Chloride

4.11.2.1 Baseline Period

Figure 47 shows the chloride mass balances for the baseline period (WY 2000-01 to 2009-10) for the Central Basin and West Coast Basin. As shown in Figure 47, recharge at the MFSG is the largest chloride load to the Central Basin, followed by irrigation return flows and subsurface inflow from neighboring basins. Deep percolation of precipitation, AGB injection, and mountain front recharge are minor chloride loading sources. Minor chloride loading associated with recharge at the DGSG in the Central Basin is included with the MFSG loading shown in Figure

47. In the Central Basin, groundwater pumping is the major chloride outflow, along with a small amount of subsurface outflow to the West Coast Basin. Annual changes in chloride mass vary from year to year but are consistently positive. There is an overall increase in cumulative chloride mass of 56,300 tons in groundwater in the Central Basin over the baseline period, equivalent to an increase of 3.3 mg/L of chloride in groundwater over the 10 years.

In the West Coast Basin, subsurface inflow from the ocean and adjacent basins is the largest chloride source, followed by irrigation return flows and injection at the seawater intrusion barriers. Smaller components of chloride loading include deep percolation of precipitation, mountain front recharge, and recharge at the DGSG. Groundwater pumping is the only chloride outflow as there is no subsurface outflow. Annual changes in chloride mass vary slightly from year to year but are consistently negative, thereby indicating a net decrease in chloride mass in groundwater. This is in contrast to the trends analysis (Table I-4), which shows more wells (35) with increasing chloride concentrations than decreasing chloride concentrations (17) and 42 wells showing no trends. The difference in results can be explained by the seawater barriers acting to prevent new seawater intrusion and lower chloride concentrations (reduced mass loading) on a basin-wide basis. This contrasted with continuing migration of the existing inland saline plumes, results in increasing concentration trends in wells downgradient of the saline plumes. The cumulative change in chloride mass in the West Coast Basin over the baseline period is a decrease of about 99,000 tons, equivalent to a decrease of 15.6 mg/L of chloride in groundwater over the 10 years.

4.11.2.2 Future Planning Period

Figures 48 through 52 illustrate the chloride mass balances for the future planning period (WY 2010-11 to 2024-25) for Scenario 1 (the No Future Projects Scenario) and Scenarios 8 through 11 (various combinations of proposed projects), respectively. Similar to TDS, for Scenarios 1 and 8 through 11, the MFSG recharge is the largest chloride loading source in the Central Basin followed by irrigation return flows and subsurface inflow. Precipitation infiltration, mountain front recharge, and AGB injection, are minor chloride loading sources. Groundwater pumping is the major chloride outflow along with a small amount of subsurface outflow to the West Coast Basin. Chloride loading is highest under scenarios that include GRIP B (Scenarios 9 and 11), with Scenario 11 having a higher chloride load than Scenario 9 due to the difference in simulated recycled water chloride concentrations. Under the No Future Projects Scenario, the cumulative (WY 2010-11 to 2024-25) chloride mass increase in groundwater is about 86,000 tons, while the chloride mass increase for Scenarios 8 through 11 ranges from 94,900 to 122,200 tons. Increases in chloride mass generally correlate to increases in average groundwater chloride concentrations, but the volume change associated with chloride mass change must also be considered. For example, while cumulative chloride mass increases under Scenario 8 are larger than under the No Future Projects Scenario (94,900 tons versus 86,000 tons), projected average chloride concentrations in groundwater in the Central Basin are slightly lower under Scenario 8 (5.0 mg/L versus 5.1 mg/L for the No Future Projects Scenario). This occurs because the water budget indicates a net positive storage change under Scenario 8 and a net negative storage change under the No Future Projects Scenario. Under Scenarios 9 through 11, the effects of combined projects result in a larger positive chloride mass increase and higher average groundwater TDS concentrations in the Central Basin compared to the No Future Projects Scenario. By the end of the 15-year planning period in WY 2024-25, the projected increase in chloride concentration in groundwater in the Central Basin under Scenarios 9 through 11 ranges from 5.6 to 6.5 mg/L; under the No Future Projects Scenario, chloride levels in groundwater are projected to increase by 5.0 mg/L over the same period.

For Scenarios 1 and 8 through 11 in the West Coast Basin (Figures 48 through 52), subsurface inflow followed by irrigation return flows and injection at the seawater barriers are the largest chloride sources. Precipitation infiltration, mountain front recharge, and recharge at the DGSG are minor chloride loading sources. Groundwater pumping is the only chloride outflow. Chloride loading is less under Scenarios 8 through 11 compared with the No Future Projects Scenario as a result of two factors: 1) reduced chloride loading from increased AWT recycled water used at the seawater barriers under Scenarios 8 through 11, and 2) increased removal of chloride mass from groundwater due to increased desalter well pumping under Scenarios 8 through 11. Under the No Future Projects Scenario, the cumulative (WY 2010-11 to 2024-25) chloride mass decrease in groundwater is about 150,200 tons, equating to a groundwater chloride concentration decrease of 23.6 mg/L over the 15-year period. In comparison, under Scenarios 8 through 11, the cumulative (WY 2010-11 to 2024-25) chloride mass decrease in groundwater ranges from 220,800 to 225,100 tons, equating to a groundwater chloride concentration decrease of 34.1 to 34.7 mg/L over the same period.

4.11.3 Nitrate

4.11.3.1 Baseline Period

Figure 53 shows the nitrate mass balances for the baseline period (WY 2000-01 to 2009-10) for the Central Basin and West Coast Basin. As shown in Figure 53, recharge at the MFSG is the largest nitrate load to the Central Basin, followed by subsurface inflow from neighboring basins. Mountain front recharge, irrigation return flows, AGB injection, and deep percolation of precipitation are minor nitrate loading sources. Minor nitrate loading associated with recharge at the DGSG in the Central Basin is included with the MFSG loading shown in Figure 53. Groundwater pumping is the major nitrate outflow, along with a small amount of subsurface outflow to the West Coast Basin. Annual changes in nitrate mass vary from year to year, but a net increase in nitrate mass in groundwater is estimated for each of the 10 years in the baseline period. Thus, there is an overall increase in nitrate mass of about 3,100 tons in the Central Basin over the 10-year baseline period, equivalent to an increase of 0.07 mg/L of nitrate-N in groundwater.

In the West Coast Basin, injection at the seawater intrusion barriers is typically the largest nitrate source followed by subsurface inflows from neighboring basins and mountain front recharge. Smaller components of nitrate loading include irrigation return flows, deep percolation of precipitation, and recharge at the DGSG. Groundwater pumping is the only nitrate outflow as there is no subsurface outflow. Annual changes in nitrate mass vary from year to year but are consistently positive. The cumulative change in nitrate-N mass in groundwater in the West Coast Basin over the 10-year baseline period is an increase of about 320 tons, equivalent to an increase of 0.04 mg/L of nitrate-N in groundwater.

4.11.3.2 Future Planning Period

Figures 54 through 58 illustrate the nitrate mass balances for the future planning period (WY 2010-11 to 2024-25) for Scenario 1 (the No Future Projects Scenario) and Scenarios 8 through 11 (various combinations of proposed projects), respectively. For Scenarios 1 and 8 through 11, recharge at the MFSG is the largest nitrate loading source to the Central Basin (due primarily to its large inflow volume relative to other inflows) followed by subsurface inflow from neighboring basins. Mountain front recharge, irrigation return flows, AGB injection, and precipitation infiltration are minor nitrate loading sources. Groundwater pumping is the major nitrate outflow along with a small amount of subsurface outflow to the West Coast Basin. Nitrate loading is highest under scenarios that include GRIP B (Scenarios 9 and 11), with Scenario 11 having a slightly higher nitrate load than Scenario 9 due to the difference in simulated recycled water nitrate concentrations. Increased nitrate loading also occurs under scenarios that include GRIP A (Scenarios 8 and 10). Under the No Future Projects Scenario, the cumulative (WY 2010-11 to 2024-25) nitrate mass increase in groundwater is about 4,700 tons, equating to a small groundwater nitrate concentration increase of 0.07 mg/L over the 15-year period. Under Scenarios 8 through 11, the nitrate mass increase in groundwater under Scenarios 8 through 11 ranges from 5,500 to 5,800 tons, equating to a groundwater nitrate concentration increase of 0.14 to 0.15 mg/L for the same period.

For Scenarios 1 and 8 through 11 in the West Coast Basin (Figures 54 through 58), injection at the seawater intrusion barriers is the largest nitrate inflow, followed by subsurface inflow from adjacent basins and mountain front recharge. Smaller components of nitrate loading include irrigation return flows, precipitation infiltration, and recharge at the DGSG. Groundwater pumping is the only nitrate outflow. Nitrate loading is similar for all five scenarios, with cumulative (WY 2010-11 to 2024-25) nitrate mass increases in groundwater ranging from 457 to 466 tons, equating to a groundwater nitrate concentration increase of 0.06 to 0.07 mg/L over the 15-year period.

5 Simulated Baseline and Future Groundwater Quality

5.1 Baseline Period Groundwater Quality Results

Figure 59 shows the simulated results of the calibrated mixing model for the baseline period of WY 2000-01 through 2009-10 for (from top to bottom) the Los Angeles Forebay, Montebello Forebay, Whittier Area, and Central Basin Pressure Area, as well as for the entire Central Basin and West Coast Basin. Each chart in Figure 59 shows the simulated average concentration for each model layer and for all model layers within the given subarea or basin. In general, the charts illustrate that the average groundwater concentrations within a given subarea and in the lower model layers (Layers 3 and 4) have not changed significantly as a result of recent historical S/N loading. These trends are consistent with the dominant actual observed well concentration trends (see Table I-4) and generally reflect the large buffering capacity of the existing groundwater in storage and the muted impact of S/N loading on the surface at lower aquifer depths. Some larger changes in S/N concentrations over time are observed in Layer 1 due to the smaller volumes of groundwater and S/N mass in these layers. Additional discussion of the baseline mixing model results are presented below by subarea.

5.1.1 Los Angeles Forebay

As depicted in the top row of Figure 59, overall average simulated concentrations within the Los Angeles Forebay (black line) for TDS, chloride, and nitrate are relatively flat, with slight overall increases in Layer 4 and an increase in nitrate in Layer 1. These trends are generally consistent with trends observed in the few Los Angeles Forebay wells for which trends could be analyzed (see Table I-3).

5.1.2 Montebello Forebay

As depicted in the second row of Figure 59, within the Montebello Forebay, simulated overall TDS concentrations (black line) decrease moderately (from 534 to 482 mg/L), while overall chloride and nitrate concentrations are generally flat. These TDS, chloride, and nitrate trends are generally consistent with trends observed in Montebello Forebay wells (see Table I-4).

5.1.3 Whittier Area

As depicted in the third row of Figure 59, overall average simulated concentrations within the Whittier Area (black line) for TDS, chloride, and nitrate are relatively flat, consistent with observed trends in the few Whittier Area wells for which trends could be analyzed (see Table I-4).

5.1.4 Central Basin Pressure Area

As depicted in the fourth row of Figure 59, overall average simulated concentrations within the Central Basin Pressure Area (black line) for TDS, nitrate, and chloride are relatively flat. These trends are consistent with observed trends in Central Basin Pressure Area wells (see Table I-4).

5.1.5 Central Basin (all subareas, not including coastal area)

Simulated concentrations in the Central Basin (including all forebay areas and the pressure area landward of the AGB) are shown in the second to bottom row on Figure 59. The simulated average concentrations for TDS, chloride, and nitrate show relatively flat to minor increasing trends over the baseline period, indicating that historical S/N loading has not significantly impacted ambient groundwater concentrations within the Central Basin as a whole. Over the 10-year baseline period, the average TDS and chloride concentrations in the Central Basin increased by about 3 and 2 mg/L, respectively, while simulated nitrate concentrations increased by 0.06 mg/L.

5.1.6 West Coast Basin (not including coastal areas)

Simulated concentrations in the West Coast Basin are shown in the bottom row on Figure 59. The overall simulated concentrations (black line) show that TDS and chloride concentrations decreased moderately over the baseline period. While there is a slight increase in nitrate-N from 0.05 to 0.10 mg/L, the magnitude of the increase is small and the overall average simulated nitrate concentration is relatively flat. TDS concentrations decreased from 890 to

875 mg/L, while chloride decreased from 306 to 290 mg/L. In contrast, TDS and chloride concentration trends in West Coast Basin wells indicate that TDS and chloride concentrations are flat to slightly increasing regionally within the West Coast Basin (Table I-4). However, a closer examination of the location of the wells with increasing trends on Figure 39 indicates that many of the wells with increasing trends are likely influenced by the migration of saline plumes associated with historical seawater intrusion across the basin and not by current TDS and chloride loading. Given that the ambient groundwater is impacted by historical seawater intrusion, and ongoing mitigation measures, including the operation of the desalters and injection of high quality water at the seawater barriers for more than 40 years, it is likely that current TDS and chloride loading is helping to lower the ambient background TDS and chloride concentrations in the West Coast Basin.

5.2 Future Planning Period Groundwater Quality Results by Subarea

Table I-19 shows the water quality changes simulated by the SNMP mixing model and percentage use of assimilative capacity between 2010 and 2025 for each scenario for each subarea and for the basins as a whole. S/N concentrations and the assimilative capacity in 2010 are represented as the existing average groundwater quality and available assimilative capacity calculated based on the last five years of water quality data (2007 to 2012), as described in Appendix G *Hydrogeologic Conceptual Model and Existing Salt and Nutrient Groundwater Quality.* Impacts to water quality and assimilative capacity were quantified and summarized in Table I-19 for the following conditions: 1) No Future Projects Scenario – average baseline conditions continued through the future planning period, 2) Overall Scenario – the indicated future project/scenario in combination with average baseline conditions continued through the future planning period, and 3) Scenario minus Baseline Conditions – the indicated future project/scenario excluding or subtracting average baseline conditions.

Figure 60 shows the simulated results for TDS in groundwater for Scenarios 1 through 11 (each including baseline conditions) from WY 2010-11 through 2024-25 for (from top to bottom) the Los Angeles Forebay, Montebello Forebay, Whittier Area, and Central Basin Pressure Area, as well as for the entire Central Basin and West Coast Basin. Each chart in Figure 60 shows the simulated TDS concentration trends for each scenario (including baseline conditions) within the indicated subarea or basin and the 10% and 20% assimilative capacity thresholds. Figures 61and 62 show the simulated concentration trends for chloride and nitrate, respectively. In the West Coast Basin, where there is no available assimilative capacity for TDS and chloride due to historical seawater intrusion, the BPO/BSBPOs are shown rather than the 10% or 20% assimilative capacity threshold. Because the projected scenario concentrations plot very close together, there is an index on the side of each chart, which shows the relative position of each scenario concentration in WY 2024-25. The results for each subarea and basin as a whole are discussed below.

Table I-19 Future Projects – Groundwater Quality Impacts and Use of Available Assimilative Capacity

FUTURE PROJECTS - CHANGE IN GROUNDWATER QUALITY AND USE OF AVAILABLE ASSIMILATIVE CAPACITY

Scenario	1. No Future Projects			2. Increased Recycled Water Irrigation (Baseline period average RW quality)						3. Increased Recycled Water Irrigation (RW quality at MCL/SMCLs)						4. Seawater Barriers						5. Desalters						6. GRIP A (Tertiary and AWT RW)

TDS - total dissolved solids
AWT - advanced water treatment
MCL - maximum contaminant level
Cl - chloride
SMCL - secondary MCL
NO_3-N - nitrate as nitrogen
mg/L - milligrams per liter
NC - No assimilative capacity available
A.C. - assimilative capacity
GRIP - Groundwater Reliability Improvement Program
GRIP A – GRIP Recycled Water Project A
GRIP B - GRIP Recycled Water Project B
Baseline - The period of time from water year 2000-01 to 2009-10 used for assessment of salt and nutrient inflows and outflows

a - “Overall Scenario” quantifies the impacts of the indicated future project/scenario in combination with existing projects in the CBWCB, i.e. including average baseline conditions (No Future Projects Scenario) continued through the future planning period

b - “Scenario minus Baseline Conditions” quantifies the impacts of the indicated future project/scenario solely, without existing projects in the CBWCB, i.e. excluding average baseline conditions (No Future Projects Scenario) or background loading

c - Positive value indicates the scenario is increasing concentrations or using additional available assimilative capacity; negative value indicates the scenario is improving groundwater quality or increasing available assimilative capacity

d -Minor Future Changes, as referenced for all combined scenarios (8, 9, 10, and 11), include decreased imported water use for supply in the Central Basin, slightly increased imported water for supply in the West Coast Basin, and increased stormwater capture at the DGSG and other facilities

e - 2010 year values used to calculate changes in concentrations and use of assimilative capacity are the average existing groundwater quality and available assimilative capacity (See Table I-11)

5.2.1 Los Angeles Forebay

As shown in Figure 60 and Table I-19, average simulated TDS concentrations in groundwater both increase and decrease very slightly over the future planning period in the Los Angeles Forebay depending on the scenario. Under the No Future Projects Scenario, TDS increases by 2.4 mg/L, equivalent to using 4.0% of the available assimilative capacity. Evidenced by the close plotting relative to the No Future Projects Scenario, TDS concentrations in the Los Angeles Forebay are insensitive to loading changes involving the seawater intrusion barriers, West Coast Basin desalter wells, and the GRIP A and GRIP B alternatives. Compared to the No Future Projects Scenario, TDS concentration increases are slightly higher under Scenarios 2 and 3 as a result of projected increases in recycled water for irrigation. Decreases in TDS concentrations observed for combined future projects (Scenarios 8 through 11) illustrate the benefit of minor future changes (specifically reduced future water use as a result of conservation) on groundwater TDS concentrations. For all scenarios, TDS concentrations remain well below the BSBPO of 700 mg/L, and single and multiple recycled water projects use less than 10% and 20% of the available assimilative capacity, respectively.

As shown in Figure 61 and Table I-19, average simulated chloride concentrations in groundwater increase between 0.8 and 2.5 mg/L over the future planning period in the Los Angeles Forebay for all scenarios, equivalent to using 1.1% to 3.7% of the available assimilative capacity. Scenarios that include increased recycled water use for irrigation (Scenarios 2 and 3) result in slightly larger increases in chloride concentration. However, such impacts are reduced under combined future projects (Scenarios 8 through 11), which incorporate the effect of background changes, including reduced overall future water use due to conservation. For all scenarios, chloride concentrations remain below the BSBPO of 150 mg/L, and single and multiple recycled water projects use less than 10% and 20% of the available assimilative capacity, respectively.

As shown in Figure 62 and Table I-19, average simulated nitrate concentrations in groundwater increase very slightly (0.15 mg/L) over the future planning period in the Los Angeles Forebay for all scenarios, equivalent to using 1.5% to 2.4% of the available assimilative capacity. Nitrate concentrations remain well below the BPO of 10 mg/L, and single and multiple recycled water projects use less than 10% and 20% of the available assimilative capacity, respectively.

5.2.2 Montebello Forebay

As shown in Figure 60 and Table I-19, average simulated TDS concentrations in groundwater decrease (between 45.7 and 66.4 mg/L) over the future planning period in the Montebello Forebay for all scenarios. The decrease in TDS concentrations are smaller for scenarios that include GRIP B (Scenario 7, 9, and 11). Nonetheless, TDS concentrations remain below the BSBPO of 700 mg/L for all scenarios, and single and multiple recycled water projects use none of the available assimilative capacity.

As shown in Figure 61 and Table I-19, average simulated chloride concentrations in groundwater both decrease and increase over the future planning period in the Montebello Forebay, depending on the scenario. Slight increases in chloride concentrations (3.6 to 4.0 mg/L) are projected for scenarios that include GRIP B (Scenarios 7, 9, and 11). Such increases are equivalent to using 5.8% to 6.4% of the available assimilative capacity; chloride concentrations decrease in all other scenarios. For all scenarios, chloride concentrations remain below the BSBPO of 150 mg/L, and single and multiple recycled water projects use less than 10% and 20% of the available assimilative capacity, respectively.

As shown in Figure 62 and Table I-19, average simulated nitrate concentrations in groundwater increase very slightly (between 0.02 and 0.22 mg/L) over the future planning period in the Montebello Forebay for all scenarios, equivalent to using 2.5% or less of the available assimilative capacity. Nitrate concentrations remain below the BPO of 10 mg/L, and single and multiple recycled water projects use less than 10% and 20% of the available assimilative capacity, respectively.

5.2.3 Whittier Area

As shown in Figure 60 and Table I-19, average simulated TDS concentrations in groundwater decrease (between 34.2 and 42.1 mg/L) over the future planning period in the Whittier Area for all scenarios. There are very minor differences between scenarios. For all scenarios, TDS concentrations remain below the BSBPO of 700 mg/L, and while some projects slightly increase TDS concentrations relative to the No Future Projects Scenario, single and multiple recycled water projects use none of the available assimilative capacity.

As shown in Figure 61 and Table I-19, average simulated chloride concentrations in groundwater decrease over the future planning period in the Whittier Area for all scenarios (between 1.8 and 3.8 mg/L). Chloride concentrations remain below the BSBPO of 150 mg/L, and while some projects slightly increase chloride concentrations relative to the No Future Projects Scenario, single and multiple recycled water projects use none of the available assimilative capacity.

As shown in Figure 62 and Table I-19, average simulated nitrate concentrations in groundwater increase very slightly (0.05 mg/L) over the future planning period for all scenarios. However, nitrate concentrations remain well below the BPO of 10 mg/L, and single and multiple recycled water projects use less than 10% and 20% of the available assimilative capacity, respectively.

5.2.4 Central Basin Pressure Area

As shown in Figure 60 and Table I-19, average simulated TDS concentrations in groundwater increase (between 18.4 and 22.9 mg/L) over the future planning period in the Central Basin Pressure Area for all scenarios, equivalent to using between 8.0% and 10.0% of the available assimilative capacity. The concentrations are similar for all scenarios including the No Future Projects Scenario. For all scenarios, TDS concentrations remain below the BSBPO of 700 mg/L, and with the exception of Scenario 3 (which uses 10% of the assimilative capacity), scenarios including single and multiple recycled water projects use less than 10% and 20% of the available assimilative capacity, respectively. It is noted that most of the TDS concentration increases occur under No Future Projects conditions, reflecting TDS loading from subsurface inflows and irrigation return flows, not recycled water projects. For example, Scenario 3 results in an additional increase of 1.5 mg/L of TDS relative to the No Future Projects Scenario, equivalent to using an additional 0.6% of the available assimilative capacity.

As shown in Figure 61 and Table I-19, average simulated chloride concentrations in groundwater increase (between 7.5 and 8.7 mg/L) over the future planning period in the Central Basin Pressure Area for all scenarios, equivalent to using between 8.0% and 9.2% of the available assimilative capacity. The chloride concentrations are similar for all scenarios, including the No Future Projects Scenario. For all scenarios, chloride concentrations remain well below the BSBPO of 150 mg/L, and single and multiple recycled water projects use less than 10% and 20% of the available assimilative capacity, respectively. Similar to TDS, most of the chloride loading is associated with No Future Projects conditions, reflecting chloride loading from subsurface inflows and irrigation return flows, not recycled water projects. For example, Scenario 3 results in an additional increase of 0.8 mg/L of chloride relative to the No Future Projects Scenario, equivalent to using an additional 0.8% of the available assimilative capacity.

As shown in Figure 62 and Table I-19, average simulated nitrate concentrations in groundwater increase very slightly (0.13 and 0.14 mg/L) over the future planning period in the Central Basin Pressure Area for all scenarios, equivalent to using between 1.3% and 1.4% of the available assimilative capacity. The nitrate concentrations are similar for all scenarios, including the No Future Projects Scenario. Most of the loading is associated with No Future Projects conditions, reflecting nitrate loading from subsurface inflows and irrigation return flows, not recycled water projects. For all scenarios, concentrations remain well below the BPO of 10 mg/L, and single and multiple recycled water projects use less than 10% and 20% of the available assimilative capacity, respectively.

5.2.5 Central Basin (all subareas, not including coastal area)

Central Basin results are similar to the Central Basin Pressure Area results because the Pressure Area contains the largest volume of groundwater compared to the other subareas within the Central Basin. As shown in Figure 60 and Table I-19, average simulated TDS concentrations in groundwater in the Central Basin increase between 0.7 and 7.7 mg/L over the future planning period for all scenarios, equivalent to using between 0.4% and 4.5% of the available assimilative capacity. TDS concentrations remain well below the BSBPO of 700 mg/L, and single and multiple recycled water projects use less than 10% and 20% of the available assimilative capacity, respectively.

As shown in Figure 261 and Table I-19, average simulated chloride concentrations in groundwater increase (between 4.8 and 6.5 mg/L) over the future planning period in the Central Basin for all scenarios, equivalent to using 5.8% to 7.8% of the available assimilative capacity. Chloride concentrations remain well below the BSBPO of 150 mg/L, and single and multiple recycled water projects use less than 10% and 20% of the available assimilative capacity, respectively.

As shown in Figure 62 and Table I-19, average simulated nitrate concentrations in groundwater increase very slightly (between 0.11 and 0.15 mg/L) over the future planning period in the Central Basin for all scenarios, equivalent to using between 1.1% and 1.5% of the available assimilative capacity. Nitrate concentrations remain well below the BPO of 10 mg/L, and single and multiple recycled water projects use less than 10% and 20% of the available assimilative capacity, respectively.

5.2.6 West Coast Basin (not including coastal areas)

As shown in Figure 60 and Table I-19, average simulated TDS concentrations in groundwater decrease (between 20.6 and 57.4 mg/L) over the future planning period in the West Coast Basin for all scenarios. However, TDS concentrations are above the BSBPO of 800 mg/L due to historical seawater intrusion, and there is no available assimilative capacity for TDS when the saline plume is included in the calculation of the basin average. Nonetheless, TDS concentrations continue to decline as a result of existing implementation measures, including the basin adjudication to limit pumping and operation of the seawater barriers and desalter facilities. Proposed implementation measures, as further discussed in Appendix J *Implementation Plan* of the SNMP, including increased injection of AWT recycled water at the seawater barriers and increased groundwater pump and treat by the desalters, are expected to further improve groundwater quality in the future.

As shown in Figure 61 and Table I-19, average simulated chloride concentrations in groundwater decrease (between 22.4 and 34.7 mg/L) over the future planning period in the West Coast Basin for all scenarios. However, chloride concentrations are above the BSBPO of 250 mg/L due to historical seawater intrusion, and there is no available assimilative capacity for chloride when the saline plume is included in the calculation of the basin average. Chloride concentrations continue to decline due to existing implementation measures, including the basin adjudication to limit pumping and operation of the seawater barriers and desalter facilities. Proposed implementation measures, as further discussed in Appendix J *Implementation Plan* of the SNMP, including increased injection of AWT recycled water at the seawater barriers and increased groundwater pump and treat by the desalters, are expected to further improve groundwater quality in the future.

As shown in Figure 62 and Table I-19, average simulated nitrate concentrations in groundwater increase very slightly (between 0.06 and 0.07 mg/L) over the future planning period in the West Coast Basin for all scenarios, equivalent to using between 0.6% and 0.7% of the available assimilative capacity. Concentrations remain well below the BPO of 10 mg/L for all scenarios. Overall, single and multiple recycled water projects use less than 10% and 20% of the available assimilative capacity, respectively.

5.3 Future Project Impacts on Groundwater Quality

Figures 14, 15, and 16 illustrate the groundwater quality impacts and use of assimilative capacity (results from Table I-19) graphically for TDS, chloride, and nitrate-N, respectively, for (from top to bottom) the Los Angeles Forebay, Montebello Forebay, Whittier Area, and Central Basin Pressure Area, as well as for the entire Central Basin and West Coast Basin. In the figures, the "Overall Scenario" results (which include baseline conditions) are depicted along the first and third columns from the left and the "Scenario minus Baseline Conditions," which provides the impacts of the indicated project/scenario in isolation of baseline conditions or background loading associated with existing projects, are depicted along the second and fourth columns from the left. Impacts in terms of the S/N concentration (two far left columns) and use of assimilative capacity (two far right columns) are provided. As shown in Figures 14 and 15, there is no available assimilative capacity in the West Coast Basin for TDS and chloride due to historical seawater intrusion. In the Whittier Area, there is no available assimilative capacity for TDS due to naturally occurring conditions associated with marine source rocks in the underlying aquifers (see Section 5.3.1.2 in the SNMP and Appendix G *Hydrogeologic Conceptual Model and Existing Salt and Nutrient Groundwater Quality* for further details).

5.3.1 Scenarios 2 and 3 – Increased Recycled Water for Irrigation

As described in Section 2.3, Scenarios 2 and 3 were simulated by the SNMP mixing model to determine potential groundwater quality impacts associated with increased use of recycled water for irrigation. For Scenario 2, S/N concentrations in the recycled water are equivalent to baseline period average concentrations. For Scenario 3, S/N concentrations in the recycled water are equivalent to the SMCLs for TDS and chloride and the MCL for nitrate, which are greater than the baseline period average S/N concentrations.

Figures 14 and 15 and Table I-19 show that increased recycled water use for irrigation only slightly increases TDS and chloride concentrations in groundwater and uses a minimal amount of the available assimilative capacity, significantly less than 10%. Thus, recycled water with higher salt concentrations (TDS and chloride at SMCLs) results in slightly higher salt loading than recycled water with baseline period average salt concentrations. The increased recycled water use for irrigation has no impact on nitrate loading (Figure 16). Overall, Figures 14 through 16 illustrate that the use of recycled water impacts all subareas and the basins has a whole at similar levels, since irrigation occurs in all areas. However, recycled water use for irrigation has minimal impacts on groundwater quality in the CBWCB and these minor impacts are more than offset by other projects that reduce S/N loading.

Because the negative water quality impacts of increased recycled water use for irrigation have been demonstrated in the SNMP to be minor and more than offset by implementation measures and projects that improve groundwater quality, the SNMP may be used to modify currently permitted recycled water quality limits established for non-potable reuse (irrigation, industrial and recreational activities) and provide a basis for streamlining the permitting process for future recycled water projects, per the Recycled Water Policy and the Governor's recent drought proclamations (refer to Section 9.3 in the SNMP). In particular, irrigation with recycled water has very minor impacts on groundwater quality and thus, permits for individual irrigation sites does not appear warranted. As a result, TDS, chloride, and nitrate standards for recycled water used for irrigation and other non-potable reuse applications can be set equivalent to SMCLs/MCL, while still protecting groundwater quality and preserving beneficial uses.

5.3.2 Scenario 4 – Seawater Intrusion Barriers

As described in Section 2.3, Scenario 4 was simulated by the SNMP mixing model to determine potential groundwater quality impacts associated with proposed seawater intrusion barrier projects that would increase injection volumes and increase the use of AWT recycled water to completely replace imported water at all three seawater barriers (AGB, DGB, and WCBB). Figures 14 and 15 and Table I-19 show that Scenario 4 would decrease TDS and chloride concentrations in the Central Basin Pressure Area, the entire Central Basin, and the entire West Coast Basin, since these are the areas where the seawater barriers are located. Scenario 4 has no impact on nitrate loading (Figure 16) because nitrate concentrations in imported water and AWT recycled water are both very low. Overall, the proposed seawater barrier projects would significantly improve TDS and chloride groundwater quality in both basins, especially in the West Coast Basin and accordingly, these projects were designated as an implementation measure, as further discussed in Appendix J *Implementation Plan* of the SNMP. As a result, this SNMP may be used to provide a basis for streamlining the permitting process for future AWT recycled water projects, per the Recycled Water Policy.

5.3.3 Scenario 5 – Desalters

As described in Section 2.3, Scenario 5 was simulated by the SNMP mixing model to determine potential groundwater quality impacts associated with proposed desalter projects that would increase the pumping and treatment of seawater-impacted groundwater in the West Coast Basin. Figures 14 and 15 and Table I-19 show that Scenario 5 would decrease TDS and chloride concentrations in the West Coast Basin, where the desalters are located. The desalters have no impact on nitrate loading (Figure 16) because nitrate concentrations in the saline plume are the same as in ambient groundwater. Overall, the proposed desalter projects would significantly improve TDS and chloride groundwater quality in the West Coast Basin and accordingly, these projects were designated as an implementation measure, as further discussed in Appendix J *Implementation Plan* of the SNMP.

5.3.4 Scenarios 6 and 7 – GRIP A and GRIP B

As stated in Section 2.3, WRD established GRIP to completely replace imported water (up to 21,000 AFY) with reliable alternative water supplies (e.g. recycled water) for recharge at the MFSG. Two project alternatives, GRIP A (Scenario 6) and GRIP B (Scenario 7), are currently being evaluated for implementation, so their potential groundwater quality impacts were simulated separately by the SNMP mixing model. Both alternatives would result in the same total recharge volumes at the MFSG; however, the recycled water quality would be different under the different scenarios.

Figures 14, 15, and 16 and Table I-19 show that impacts from the GRIP scenarios are greatest in the Montebello Forebay, where the project will be implemented. GRIP A has negligible impacts on groundwater quality, decreasing TDS slightly and increasing chloride and nitrate very slightly in the Central Basin. This is because the AWT/tertiary-treated recycled water blend ratio for GRIP A mirrors the average imported water quality that it is replacing for recharge at the MFSG. GRIP B would increase TDS, chloride, and nitrate concentrations compared with the No Future Projects Scenario. However, GRIP B would not cause S/N concentrations to exceed BPO/BSBPOs or utilize more than 10% of the available assimilative capacity in the Central Basin. Minor negative groundwater quality impacts associated with GRIP B are more than offset by the positive impacts of other projects and implementation measures.

While groundwater quality impacts from GRIP B are greater than GRIP A, the costs of GRIP A are significantly higher than GRIP B. As presented in Appendix J *Implementation Plan* in the SNMP, estimated costs for GRIP A are $779M, while estimated costs for GRIP B are $182M (CH2MHILL, 2012a)[2]. Thus, water quality benefits must be weighed against costs and other evaluation criteria. Because of the negligible impacts of GRIP A and the minor negative water quality impacts of GRIP B overall in the Central Basin, this SNMP may be used to provide a basis for streamlining the permitting process for GRIP projects (and other recycled water projects) in the future, per the Recycled Water Policy and the Governor's recent drought proclamations (refer to Section 9.3 in the SNMP).

5.3.5 Scenarios 8, 9, 10, and 11 – Combined Projects/Scenarios

As described in Section 2.3, Scenarios 8 through 11 were simulated by the SNMP mixing model to determine potential groundwater quality impacts associated with combinations of proposed projects/scenarios, which also include minor future changes (i.e. increased and decreased imported water for supply in the West Coast Basin and Central Basin, respectively, and increased stormwater capture). Figures 14, 15, and 16 and Table I-19 show that Scenarios 8 through 11 would result in small increases in TDS, chloride, and nitrate concentrations in groundwater in the Central Basin. However, S/N concentrations do not exceed BPO/BSBPOs by 2025 and multiple recycled water projects do not utilize more than 20% (or even 10%) of the available assimilative capacity in the Central Basin. In the West Coast Basin, Scenarios 8 through 11 would result in decreasing TDS and chloride concentrations in groundwater. There is a very small increase in nitrate concentrations, which is insignificant given the very low nitrate concentration in ambient groundwater.

5.3.6 Summary of Impacts of Future Scenarios

Table I-20 summarizes overall changes in groundwater quality, impacts on BPO/BSBPOs, and use of assimilative capacity for each of the scenarios in terms of TDS, chloride, and nitrate in groundwater in the Central Basin. The table quantifies the impacts of average baseline conditions continued through the future planning period (No Future Projects Scenario) plus the indicated future project or project combinations. **Table I-21** quantifies the impacts of future project(s) solely, i.e. excluding the impact of average baseline conditions continued through the future planning period. Thus, Table I-20 illustrates total impacts, while Table I-21 illustrates the impacts of just the project or combined projects without the contributions of baseline conditions or background loading associated with existing projects. **Tables I-22** and **I-23** show similar predictions for the West Coast Basin for the overall scenarios and for the isolated project or project combinations, respectively. Increased Stormwater Capture is listed as a scenario in Tables I-20 through I-23 to summarize the expected general impacts. Because stormwater capture projects could not be quantified in terms of increased recharge volumes and S/N concentrations (with the exception of stormwater capture in the MFSG and DGSG), this scenario could not be simulated by the SNMP mixing model. Nonetheless, increased

---

[2] Capital costs include construction of treatment and conveyance facilities; injection; flow equalization; sewer connection fees, and flow diversion costs; and O&M costs including facilities O&M, recycled water purchase, and sewer surcharge fee.

Table I-20 Summary of Groundwater Quality Impacts of Overall Future Scenarios [b] in the Central Basin in 2025

Scenario [a]	CENTRAL BASIN WATER QUALITY IMPACTS IN 2025								
	TDS			Chloride			Nitrate-N		
	Concentration	BSBPO 700 mg/L	Use of AC	Concentration	BSBPO 150 mg/L	Use of AC	Concentration	BPO 10 mg/L	Use of AC
1. No Future Projects (baseline conditions only)	Increase 4.6 mg/L	Not exceeded	2.7%	Increase 5.1 mg/L	Not exceeded	6.1%	Increase 0.11 mg/L	Not exceeded	1.1%
	NOT A CONCERN (BELOW BSBPO) Projected concentration of 533 mg/L and AC of 167 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 72 mg/L and AC of 78 mg/L in 2025			NOT A CONCERN (BELOW BPO) Projected concentration of 0.39 mg/L and AC of 9.61 mg/L in 2025		
2. Increased Recycled Water for Irrigation (baseline period average WQ)	Increase 5.8 mg/L	Not exceeded	3.4%	Increase 5.4 mg/L	Not exceeded	6.4%	Increase 0.11 mg/L	Not exceeded	1.1%
	NOT A CONCERN (BELOW BSBPO) Projected concentration of 534 mg/L and AC of 166 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 72 mg/L and AC of 78 mg/L in 2025			NOT A CONCERN (BELOW BPO) Projected concentration of 0.39 mg/L and AC of 9.61 mg/L in 2025		
3. Increased Recycled Water for Irrigation (WQ at SMCLs/MCL)	Increase 6.2 mg/L	Not Exceeded	3.6%	Increase 5.9 mg/L	Not exceeded	7.1%	Increase 0.11 mg/L	Not exceeded	1.1%
	NOT A CONCERN (BELOW BSBPO) Projected concentration of 535 mg/L and AC of 165 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 73 mg/L and AC of 77 mg/L in 2035			NOT A CONCERN (BELOW BPO) Projected concentration of 0.39 mg/L and AC of 9.61 mg/L in 2025		
4. Seawater Barriers (increased injection volume and AWT RW)	Increase 2.8 mg/L	Not exceeded	1.6%	Increase 4.8 mg/L	Not exceeded	5.8%	Increase 0.11 mg/L	Not exceeded	1.1%
	NOT A CONCERN (BELOW BSBPO) Projected concentration of 531 mg/L and AC of 169 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 71 mg/L and AC of 79 mg/L in 2025			NOT A CONCERN (BELOW BPO) Projected concentration of 0.39 mg/L and AC of 9.61 mg/L in 2025		
5. Desalters (increased groundwater pump and treat)	Increase 4.6 mg/L	Not Exceeded	2.7%	Increase 5.1 mg/L	Not exceeded	6.1%	Increase 0.11 mg/L	Not exceeded	1.1%
	NOT A CONCERN (BELOW BSBPO) Projected concentration of 533 mg/L and AC of 167 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 72 mg/L and AC of 78 mg/L in 2025			NOT A CONCERN (BELOW BPO) Projected concentration of 0.39 mg/L and AC of 9.61 mg/L in 2025		
6. GRIP A (10K AFY AWT & 11K tertiary-treated RW)	Increase 4.1 mg/L	Not Exceeded	2.4%	Increase 5.5 mg/L	Not exceeded	6.6%	Increase 0.14 mg/L	Not exceeded	1.4%
	NOT A CONCERN (BELOW BSBPO) Projected concentration of 533 mg/L and AC of 167 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 72 mg/L and AC of 78 mg/L in 2025			NOT A CONCERN (BELOW BPO) Projected concentration of 0.42 mg/L and AC of 9.58 mg/L in 2025		
7. GRIP B (21K AFY tertiary-treated RW)	Increase 7.7 mg/L	Not exceeded	4.5%	Increase 6.4 mg/L	Not exceeded	7.7%	Increase 0.15 mg/L	Not exceeded	1.5%
	NOT A CONCERN (BELOW BSBPO) Projected concentration of 536 mg/L and AC of 164 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 73 mg/L and AC of 77 mg/L in 2025			NOT A CONCERN (BELOW BPO) Projected concentration of 0.43 mg/L and AC of 9.57 mg/L in 2025

10. Combined Scenarios (3 + 4 + 5 + 6 + Minor Future Changes)	Increase 1.1 mg/L	Not exceeded	0.7%	Increase 5.6 mg/L	Not exceeded	6.7%	Increase 0.14 mg/L	Not exceeded	1.4%
	NOT A CONCERN (BELOW BSBPO) Projected concentration of 530 mg/L and AC of 170 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 72 mg/L and AC of 78 mg/L in 2025			NOT A CONCERN (BELOW BPO) Projected concentration of 0.42 mg/L and AC of 9.58 mg/L in 2025		
11. Combined Scenarios (3 + 4 + 5 + 7 + Minor Future Changes)	Increase 4.7 mg/L	Not exceeded	2.8%	Increase 6.5 mg/L	Not exceeded	7.8%	Increase 0.15 mg/L	Not exceeded	1.5%
	NOT A CONCERN (BELOW BSBPO) Projected concentration of 533 mg/L and AC of 167 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 73 mg/L and AC of 77 mg/L in 2025			NOT A CONCERN (BELOW BPO) Projected concentration of 0.43 mg/L and AC of 9.57 mg/L in 2025		
Increased Stormwater Capture	Decrease	Not exceeded	Not available	Decrease	Not exceeded	Not available	Decrease	Not exceeded	Not available

a – Minor Future Changes, as referenced for all combined scenarios (8, 9, 10, and 11), include decreased imported water use for supply in the Central Basin, slightly increased imported water for supply in the West Coast Basin, and increased stormwater capture at the DGSG and other facilities

b - Quantifies the impacts of average baseline conditions continued through the future planning horizon (No Future Projects Scenario) plus the indicated future project/scenario

WQ – water quality
MCL – primary maximum contaminant level
SMCL – secondary maximum contaminant level
mg/L – milligrams per liter
Nitrate-N – nitrate as nitrogen
TDS – total dissolved solids
BPO – Basin Plan Objective
BSBPO – Basin-Specific Basin Plan Objective
GRIP – Groundwater Reliability Improvement Program
GRIP A – GRIP Recycled Water Project A
GRIP B – GRIP Recycled Water Project B
DGSG – Dominguez Gap Spreading Grounds
AWT – advanced water treatment
RW – recycled water
AC – assimilative capacity
AFY – acre-feet per year
K – thousands

(green box) – groundwater quality improvement
(orange box) – groundwater quality decline

Table I-21 Summary of Groundwater Quality Impacts of Future Scenarios Minus Baseline Conditions [b] in the Central Basin in 2025

Scenario [a]	CENTRAL BASIN WATER QUALITY IMPACTS IN 2025								
	TDS			Chloride			Nitrate-N		
	Concentration	BSBPO 700 mg/L	Use of AC	Concentration	BSBPO 150 mg/L	Use of AC	Concentration	BPO 10 mg/L	Use of AC
1. No Future Projects (baseline conditions only)	Increase 4.6 mg/L	Not exceeded	2.7%	Increase 5.1 mg/L	Not exceeded	6.1%	Increase 0.11 mg/L	Not exceeded	1.1%
	NOT A CONCERN (BELOW BSBPO) Projected concentration of 533 mg/L and AC of 167 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 72 mg/L and AC of 78 mg/L in 2025			NOT A CONCERN (BELOW BPO) Projected concentration of 0.39 mg/L and AC of 9.61 mg/L in 2025		
2. Increased Recycled Water for Irrigation (baseline average WQ)	Increase 1.2 mg/L	Not exceeded	0.7%	Increase 0.3 mg/L	Not exceeded	0.3%	No change 0.0 mg/L	Not exceeded	0%
	NOT A CONCERN (BELOW BSBPO) Projected concentration of 530 mg/L and AC of 170 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 67 mg/L and AC of 83 mg/L in 2025			NO EFFECT ON WQ Projected concentration of 0.28 mg/L and AC of 9.72 mg/L in 2025		
3. Increased Recycled Water for Irrigation (MCL or SMCL WQ)	Increase 1.6 mg/L	Not Exceeded	0.9%	Increase 50.8 mg/L	Not exceeded	1.0%	No Change 0.0 mg/L	Not exceeded	0%
	NOT A CONCERN (BELOW BSBPO) Projected concentration of 530 mg/L and AC of 170 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 67 mg/L and AC of 83 mg/L in 2035			NO EFFECT ON WQ Projected concentration of 0.28 mg/L and AC of 9.72 mg/L in 2025		
4. Seawater Barriers (increased injection volume and AWT RW)	Decrease -1.8 mg/L	Not exceeded	-1.1%	Decrease -0.3 mg/L	Not exceeded	-0.3%	No change 0.0 mg/L	Not exceeded	0%
	WQ IMPROVEMENT Projected concentration of 527 mg/L and AC of 173 mg/L in 2025			WQ IMPROVEMENT Projected concentration of 66 mg/L and AC of 84 mg/L in 2025			NO EFFECT ON WQ Projected concentration of 0.28 mg/L and AC of 9.72 mg/L in 2025		
5. Desalters (increased groundwater pump and treat)	No Change 0.0 mg/L	Not Exceeded	0%	No change 0.0 mg/L	Not exceeded	0%	No change 0.0 mg/L	Not exceeded	0%
	NO EFFECT ON WQ Projected concentration of 529 mg/L and AC of 171 mg/L in 2025			NO EFFECT ON WQ Projected concentration of 67 mg/L and AC of 83 mg/L in 2025			NO EFFECT ON WQ Projected concentration of 0.28 mg/L and AC of 9.72 mg/L in 2025		
6. GRIP A (10K AFY AWT & 11K tertiary-treated RW)	Decrease -0.5 mg/L	Not Exceeded	-0.3%	Increase 0.4 mg/L	Not exceeded	0.5%	Increase 0.03 mg/L	Not exceeded	0.3%
	WQ IMPROVEMENT Projected concentration of 528 mg/L and AC of 172 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 67 mg/L and AC of 83 mg/L in 2025			NOT A CONCERN (BELOW BPO) Projected concentration of 0.31 mg/L and AC of 9.69 mg/L in 2025		
7. GRIP B (21K AFY tertiary-treated RW)	Increase 3.1 mg/L	Not exceeded	1.8%	Increase 1.3 mg/L	Not exceeded	1.5%	Increase 0.04 mg/L	Not exceeded	0.4%
	NOT A CONCERN (BELOW BSBPO) Projected concentration of 532 mg/L and AC of 168 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 68 mg/L and AC of 82 mg/L in 2025			NOT A CONCERN (BELOW BPO) Projected concentration of 0.32 mg/L and AC of 9.68 mg/L in 2025		
8. Combined Scenarios (2 + 4 + 5 + 6 + Minor Future Changes)	Decrease -4.0 mg/L	Not Exceeded	-2.3%	Decrease -0.1 mg/L	Not exceeded	-0.1%	Increase 0.03 mg/L	Not exceeded	0.3%
	WQ IMPROVEMENT Projected concentration of 525 mg/L and AC of 175 mg/L in 2025			WQ IMPROVEMENT Projected concentration of 67 mg/L and AC of 83 mg/L in 2025			NOT A CONCERN (BELOW BPO) Projected concentration of 0.31 mg/L and AC of 9.69 mg/L in 2025		
9. Combined Scenarios (2 + 4 + 5 + 7 + Minor Future Changes)	Decrease -0.4 mg/L	Not exceeded	-0.2%	Increase 0.8 mg/L	Not exceeded	0.9%	Increase 0.04 mg/L	Not exceeded	0.4%
	WQ IMPROVEMENT Projected concentration of 528 mg/L and AC of 172 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 67 mg/L and AC of 83 mg/L in 2025			NOT A CONCERN (BELOW BPO) Projected concentration of 0.32 mg/L and AC of 9.68 mg/L in 2025		
10. Combined Scenarios (3 + 4 + 5 + 6 + Minor Future Changes)	Decrease -3.5 mg/L	Not exceeded	-2.0%	Increase 0.5 mg/L	Not exceeded	0.6%	Increase 0.03 mg/L	Not exceeded	0.3%
	WQ IMPROVEMENT Projected concentration of 525 mg/L and AC of 175 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 67 mg/L and AC of 83 mg/L in 2025			NOT A CONCERN (BELOW BPO) Projected concentration of 0.31 mg/L and AC of 9.69 mg/L in 2025		
11. Combined Scenarios (3 + 4 + 5 + 7 + Minor Future Changes)	Increase 0.1 mg/L	Not exceeded	0.1%	Increase 1.3 mg/L	Not exceeded	1.6%	Increase 0.04 mg/L	Not exceeded	0.4%
	NOT A CONCERN (BELOW BSBPO) Projected concentration of 529 mg/L and AC of 171 mg/L in 2025			NOT A CONCERN (BELOW BSBPO) Projected concentration of 68 mg/L and AC of 82 mg/L in 2025			NOT A CONCERN (BELOW BPO) Projected concentration of 0.32 mg/L and AC of 9.68 mg/L in 2025		
Increased Stormwater Capture	Decrease	Not exceeded	Not available	Decrease	Not exceeded	Not available	Decrease	Not exceeded	Not available

a – Minor Future Changes, as referenced for all combined scenarios (8, 9, 10, and 11), include decreased imported water use for supply in the Central Basin, slightly increased imported water for supply in the West Coast Basin, and increased stormwater capture at the DGSG and other facilities

b - Quantifies the impacts of average baseline conditions continued through the future planning horizon (No Future Projects Scenario) plus the indicated future project/scenario

WQ – water quality
MCL – primary maximum contaminant level
SMCL – secondary maximum contaminant level

(peach) – groundwater quality decline

stormwater capture is expected to improve groundwater quality due to the relatively high quality water associated with surface water and stormwater. Various enhanced stormwater capture projects are in place and planned for the CBWCB and the new Waste Discharge Requirements for Municipal Separate Sewer System (MS4) discharges within the coastal watersheds of Los Angeles County are expected to result in increased stormwater recharge and improved surface water quality (LARWQCB, 2012b) and thus, were designated as implementation measures (see Appendix J of the SNMP).

While some scenarios increase S/N concentrations, the increases over the future planning period are small and S/N concentrations will not exceed BPO/BSBPOs in the Central Basin. Additionally, multiple recycled water projects do not use more than 20% (or even 10%) of the available assimilative capacity. Future projects generally will improve groundwater quality in the West Coast Basin. While increased recycled water for irrigation will increase S/Ns in groundwater during the future planning period, the increases are very small. Due to existing elevated TDS and chloride concentrations in the West Coast Basin associated with historical seawater intrusion, there is no available assimilative capacity for these constituents. Nonetheless, TDS and chloride concentrations are anticipated to achieve BPO/BSBPOs beyond the future planning period as discussed in Section 5.4 *Groundwater Quality Projections Beyond WY 2024-25*.

5.4 Groundwater Quality Projections Beyond Water Year 2024-25

When groundwater quality projections were presented at the December 2012 CBWCB SNMP Stakeholder Workshop, two questions were raised by the CBWCB stakeholders:

- When will TDS and chloride in the West Coast Basin reach BSBPOs?
- Will the 20% assimilative capacity threshold for TDS and chloride be reached in the Central Basin Pressure Area in the future?

In order to answer these questions, the SNMP mixing model was used to simulate future conditions through WY 2049-50. It is noted, that as projections are extended into the future, uncertainties increase with respect to underlying baseline condition assumptions and future projects and implementation measures. Therefore, the projected dates are considered estimates. Figures I-D-1, I-D-2, and I-D-3 in **Attachment I-D** show TDS, chloride, and nitrate concentrations in groundwater, respectively, projected out to WY 2049-50. Based on the analysis, the BSBPO for TDS (800 mg/L) and chloride (250 mg/L) are estimated to be reached by about 2034 and 2035, respectively, under Scenarios 8 through 11 (combined projects/scenarios) in the West Coast Basin.

The WY 2049-50 projections indicate that the 20% assimilative capacity threshold for TDS and chloride in the Central Basin Pressure Area (or any other subareas or basins) are not anticipated to be reached by WY 2049-50 under the combined scenarios. TDS and chloride concentrations show asymptotic trends or a leveling off of the increasing trends in the future.

The simulation of water quality conditions through WY 2049-50 was conducted solely for informational purposes. As part of the 10-year periodic review of the SNMP, basin conditions will be updated based on the most current available data and groundwater quality projections will be adjusted accordingly.

6 Anti-Degradation Assessment

Section 9 *Anti-Degradation* of the SWRCB Recycled Water Policy states:

a. *The State Water Board* [SWRCB] *adopted Resolution No. 68-16 as a policy statement to implement the Legislature's intent that waters of the state shall be regulated to achieve the highest water quality consistent with the maximum benefit to the people of the state.*

b. *Activities involving the disposal of waste that could impact high quality waters are required to implement best practicable treatment or control of the discharge necessary to ensure that pollution or nuisance will not occur, and the highest water quality consistent with the maximum benefit to the people of the state will be maintained.*

c. *Groundwater recharge with recycled water for later extraction and use in accordance with this Policy and state and federal water quality law is to the benefit of the people of the state of California. Nonetheless, the State Water Board finds that groundwater recharge projects using recycled water have the potential to lower water quality within a basin. The proponent of a groundwater recharge project must demonstrate compliance with Resolution No. 68-16. Until such time as a salt/nutrient management plan is in effect, such compliance may be demonstrated as follows:*

   (1) A project that utilizes less than 10 percent of the available assimilative capacity in a basin/sub-basin (or multiple projects utilizing less than 20 percent of the available assimilative capacity in a basin/sub-basin) need only conduct an antidegradation analysis verifying the use of the assimilative capacity. For those basins/sub-basins where the Regional Water Boards have not determined the baseline assimilative capacity, the baseline assimilative capacity shall be calculated by the initial project proponent, with review and approval by the Regional Water Board, until such time as the salt/nutrient plan is approved by the Regional Water Board and is in effect. For compliance with this subparagraph, the available assimilative capacity shall be calculated by comparing the mineral water quality objective with the average concentration of the basin/sub-basin, either over the most recent five years of data available or using a data set approved by the Regional Water Board Executive Officer. In determining whether the available assimilative capacity will be exceeded by the project or projects, the Regional Water Board shall calculate the impacts of the project or projects over at least a ten year time frame.

   (2) In the event a project or multiple projects utilize more than the fraction of the assimilative capacity designated in subparagraph (1), then a Regional Water

Board-deemed acceptable antidegradation analysis shall be performed to comply with Resolution No. 68-16. The project proponent shall provide sufficient information for the Regional Water Board to make this determination. An example of an approved method is the method used by the State Water Board in connection with Resolution No. 2004-0060 and the Regional Water Board in connection with Resolution No. R8-2004-0001. An integrated approach (using surface water, groundwater, recycled water, stormwater, pollution prevention, water conservation, etc.) to the implementation of Resolution No. 68-16 is encouraged.

d. *Landscape irrigation with recycled water in accordance with this Policy is to the benefit of the people of the State of California. Nonetheless, the State Water Board finds that the use of water for irrigation may, regardless of its source, collectively affect groundwater quality over time. The State Water Board intends to address these impacts in part through the development of salt/nutrient management plans described in paragraph 6.*

   (1) A project that meets the criteria for a streamlined irrigation permit and is within a basin where a salt/nutrient management plan satisfying the provisions of paragraph 6(b) is in place may be approved without further antidegradation analysis, provided that the project is consistent with that plan.

   (2) A project that meets the criteria for a streamlined irrigation permit and is within a basin where a salt/nutrient management plan satisfying the provisions of paragraph 6(b) is being prepared may be approved by the Regional Water Board by demonstrating through a salt/nutrient mass balance or similar analysis that the project uses less than 10 percent of the available assimilative capacity as estimated by the project proponent in a basin/sub-basin (or multiple projects using less than 20 percent of the available assimilative capacity as estimated by the project proponent in a basin/sub-basin).

Average TDS, chloride, and nitrate concentrations in the Central Basin and West Coast Basin and the available assimilative capacities were estimated and discussed in Appendix G *Hydrogeologic Conceptual Model and Existing Salt and Nutrient Groundwater Quality* and are summarized in Table I-11. Table I-19 presents the change in groundwater quality for TDS, chloride, and nitrate in the Central Basin due to the implementation of individual proposed projects (Scenarios 2 through 7) and the implementation of these projects in combination (Scenarios 8 through 11) during the future planning period through WY 2024-25. As shown in Table I-19, no individual project uses more than 10% of the available assimilative capacity and multiple projects (Scenarios 8 through 11) also use less than 10% of the assimilative capacity. The analysis of Scenarios 2 and 3 (increased recycled water for irrigation with S/N concentrations at baseline period averages and at SMCLs/MCL) shows that recycled water irrigation is a small component of S/N loading and that even at higher concentrations than those stipulated in current recycled water irrigation permits, these proposed projects do not use more than 10% of the available assimilative capacity. The analysis also shows that while Scenario 7 (GRIP B – 21,000 AFY of tertiary-treated recycled water to replace imported water) uses more of the available assimilative capacity compared with Scenario 1 (No Future Projects) and Scenario 6 (GRIP A – 21,000 AFY of a blend of AWT and tertiary-treated recycled water to replace imported water), Scenario 7 does not use more than 10% of the available assimilative capacity and Scenarios 9 and 11 (GRIP B combined with proposed recycled water and other projects) also use less than 10% of the available assimilative capacity.

Table I-19 presents the change in groundwater quality for TDS, chloride, and nitrate in the West Coast Basin due to the implementation of individual proposed projects (Scenarios 2 through 7) and the implementation of these projects in combination (Scenarios 8 through 11) during the future planning period through WY 2024-25. Due to historical seawater intrusion in the CBWCB, average TDS and chloride concentrations in groundwater in the West Coast Basin currently exceed BSBPOs, so there is no available assimilative capacity for TDS and chloride. Nonetheless, existing implementation measures, including the basin adjudication to limit pumping and ongoing operation of the seawater barriers and desalter facilities have resulted in declining TDS and chloride concentrations in the West Coast Basin. In addition, implementation of Scenario 4 (increased recharge of AWT recycled water at the seawater barriers to replace imported water) further reduces TDS and chloride loading and improves groundwater quality in the CBWCB. Existing and planned implementation measures will result in average groundwater quality in the West Coast Basin achieving BSBPOs for TDS and chloride in the future.

In addition to the minimal negative, and in some cases positive, water quality impacts associated with the proposed recycled water projects in the CBWCB, the Recycled Water Policy and the Governor's recent drought proclamations (see Section 9.3 in the SNMP) recognize the tremendous need for and benefits of increased recycled water use in California. As stated in the Recycled Water Policy, "*The collapse of the Bay-Delta ecosystem, climate change, and continuing population growth have combined with a severe drought on the Colorado River and failing levees in the Delta to create a new reality that challenges California's ability to provide the clean water needed for a healthy environment, a healthy population and a healthy economy, both now and in the future. . . . We strongly encourage local and regional water agencies to move toward clean, abundant, local water for California by emphasizing appropriate water recycling, water conservation, and maintenance of supply infrastructure and the use of stormwater (including dry-weather urban runoff) in these plans; these sources of supply are drought-proof, reliable, and minimize our carbon footprint and can be sustained over the long-term.*" (SWRCB, 2009)

Clearly, the benefits in terms of sustainability and reliability of recycled water use cannot be overstated. The SNMP analysis finds that AWT recycled water is one of the highest quality source waters available (higher quality than imported water in terms of TDS and chloride) and that use of AWT recycled water is a critical component in achieving WQOs/BPOs and preserving beneficial uses in the West Coast Basin where historical seawater intrusion has degraded groundwater quality in certain areas. Tertiary-treated recycled water is also a critical component of the water supply portfolio in the CBWCB and its use can be safely increased, including implementation of higher S/N loading projects including GRIP B (which has higher S/N loading compared with GRIP A) and the increased use of recycled water for irrigation with S/N concentrations equivalent to SMCLs/MCL (which results in higher S/N loading compared with recycled water at baseline period S/N averages), while still protecting groundwater quality and preserving beneficial uses. Increased use of recycled water reduces reliance on potable water supplies, in particular increasingly uncertain and costly imported water supplies. Thus, the increased use of recycled water ensures that the water supply in the CBWCB is sustainable through the future. **Table I-24** presents the results of the anti-degradation assessment of the proposed recycled projects in the CBWCB in accordance with SWRCB Resolution No. 68-16 (Anti-Degradation Policy).

Table I-24 Anti-Degradation Assessment

SWRCB Resolution No. 68-16 Component	Anti-Degradation Assessment Result
Water quality changes associated with proposed recycled water project(s) are consistent with the maximum benefit of the people of the State. The water quality changes associated with proposed recycled water project(s) will not unreasonably affect present and anticipated beneficial uses. The water quality changes will not result in water quality less than prescribed in the Basin Plan.	• Water quality changes associated with proposed recycled water projects in the Central Basin and West Coast Basin (CBWCB) are consistent with the maximum benefit of the people of the State. • The water quality changes associated with proposed recycled water projects in the CBWCB will not unreasonably affect present and anticipated beneficial uses. • The water quality changes associated with proposed recycled water projects in the CBWCB will not result in water quality less than prescribed in the Basin Plan. • GRIP A and GRIP B will not use more than 10% of the available AC in the Central Basin. • GRIP A and GRIP B will not cause groundwater quality to exceed BPO/BSBPOs in the Central Basin. • Use of recycled water for GRIP A and GRIP B to replace imported water is consistent with the SWRCB Recycled Water Policy, which encourages reliance on local, drought-proof water supplies. • Seawater intrusion barrier projects are utilizing AWT recycled water and imported water improve groundwater quality in both basins. • Use of recycled water at the seawater intrusion barriers to replace imported water is consistent with the SWRCB Recycled Water Policy, which encourages increased reliance on local, drought-proof water sources. • Recycled water used for irrigation will not use more than 10% of the available AC in either basin. • Recycled water used for irrigation will not cause groundwater quality to exceed BPO/BSBPOs. • Use of recycled water for irrigation to replace imported water and groundwater is consistent with the SWRCB Recycled Water Policy, which encourages increased reliance on local, drought-proof water sources.

SWRCB Resolution No. 68-16 Component	Anti-Degradation Assessment Result
The projects are consistent with the use of best practicable treatment or control to avoid pollution or nuisance and maintain the highest water quality consistent with the maximum benefit to the people of the State.	• The proposed recycled water projects in the CBWCB are consistent with the use of the best practicable treatment or control to avoid pollution or nuisance and maintain the highest water quality consistent with the maximum benefit to the people of the State. • The proposed GRIP recycled water project will use either tertiary-treated and/or AWT recycled water; higher loading associated with GRIP B will not use more than 10% of the available (AC) or cause groundwater to exceed BPO/BSBPOs. • The benefit to the people of the State for GRIP A versus GRIP B must consider the significantly higher costs associated with production and use of AWT recycled water. • The ongoing seawater intrusion barrier projects currently use AWT recycled water. • Recycled water used for irrigation is currently tertiary-treated and this is the appropriate level of treatment for this very minor component of S/N loading, as determined from the SNMP analysis.
The proposed project(s) is necessary to accommodate important economic or social development.	• The proposed recycled water projects in the CBWCB are necessary to accommodate important economic and social development. • Given the uncertainties and increasing costs of imported water, increasing use of recycled water ensures a diversified and more reliable water supply. • The proposed GRIP Recycled Water Project provides a sustainable and reliable water source to replenish the groundwater basins, maintains high-quality groundwater, complies with pertinent regulatory requirements by employing an institutionally feasible approach, minimizes costs to agencies using groundwater, and engages stakeholders in the decision-making process. • Ongoing operation of the seawater intrusion barriers are necessary to prevent seawater intrusion and replenish the groundwater basins.
Implementation measures are being or will be implemented to help achieve BPOs in the future.	• Implementation measures are being implemented and additional implementation measures have been proposed in the CBWCB to help achieve or remain below BPO/BSBPOs in the future. • BPO/BSBPOs are being achieved and will not be exceeded in the Central Basin. • The ongoing operation of the seawater intrusion barriers and desalters are improving groundwater quality in the West Coast Basin and TDS and chloride levels will eventually achieve BSBPOs.

CBWCB – Central Basin and West Coast Basin
GRIP – Groundwater Reliability Improvement Program
GRIP A – GRIP Recycled Water Project A; this project alternative utilizes a blend of tertiary-treated & AWT recycled water to replace imported water for recharge at the Montebello Forebay Spreading Grounds
GRIP B – GRIP Recycled Water Project B; this project alternative utilizes 100% tertiary-treated recycled water to replace imported water for recharge at the Montebello Forebay Spreading Grounds
BPO – Basin Plan Objective
SNMP – Salt and Nutrient Management Plan
SWRCB – State Water Resources Control Board
AC – assimilative capacity
BSBPOs – Basin-Specific Basin Plan Objectives
S/Ns – salts and nutrients
AWT – advanced water treatment

Attachment I-A

Description of Mann-Kendall Trend Test

The Mann-Kendall statistical trend test is a nonparametric test that is commonly used to detect trends in a concentration time-series plot that contains the relative magnitudes of sample data. The Mann-Kendall test is particularly applicable to groundwater quality evaluations because the test is statistically robust and can be effectively applied to data sets with censored values (i.e., non-detects). For datasets with more than 10 values, the normal approximation to the Mann-Kendall test was performed using Minitab 15 and the Minitab macro MKTREND. For each dataset, the Sen's Slope, a nonparametric alternative for estimating a slope, was also calculated using Minitab 15 and the Minitab macro SENSLOPE. The Sen's Slope represents the median slope for all the pairs of time points in a dataset. For each Mann-Kendall test, an appropriate method was applied to censored data. Depending on the data distribution, any censored data with a reporting limit exceeding the lowest detected value in a given dataset was either removed or assigned a consistent concentration below the lowest detected value in the given dataset.

For the Mann-Kendall test, positive values of S, Z, and Sen's Slope suggest a possible increasing concentration trend, while negative values suggest a possible decreasing trend. A value of zero for S, Z, and Sen's Slope suggests no trend. A 95 percent confidence interval (p-value = 0.05) was used to define a level of significance; p-values less than 0.05 represent a very significant trend. P-values less than 0.10 may also suggest a trend, while trends for series with p-values greater than 0.10 are considered statistically insignificant.

Baseline and Future Salt and Nutrient Balance Tables

List of Tables

Table I-C-1 TDS Balance for Central Basin – Baseline Period

CENTRAL BASIN GROUNDWATER TDS BALANCE											
Water Year	**2000-01**	**2001-02**	**2002-03**	**2003-04**	**2004-05**	**2005-06**	**2006-07**	**2007-08**	**2008-09**	**2009-10**	**Average**
Inflow of TDS Mass to Groundwater (in tons)											
Spreading Grounds	62,304	80,722	69,001	53,213	79,173	88,504	60,568	50,083	44,366	70,873	65,880
Seawater Barrier	2,090	3,333	1,953	2,207	1,804	567	660	3,156	4,093	2,404	2,227
Precipitation Infiltration	5,067	0	5,087	2,620	5,159	3,635	82	5,198	2,983	4,462	3,429
Mountain Front Recharge	3,248	0	3,248	1,331	2,693	4,658	938	2,624	1,639	1,532	2,191
Irrigation Return Flows	29,980	36,283	31,346	32,487	29,401	28,889	30,401	33,996	32,598	31,047	31,643
Subsurface Inflow	26,111	29,934	27,187	30,008	21,632	25,875	30,974	31,433	35,973	35,657	29,478
Total Inflow	128,800	150,271	137,823	121,866	139,863	152,129	123,623	126,490	121,652	145,974	134,849
Outflow of TDS Mass from Groundwater (in tons)											
Groundwater Production	-130,175	-133,676	-126,435	-132,801	-125,559	-126,454	-131,083	-135,824	-129,100	-129,309	-130,042
Subsurface Outflow	-4,862	-4,789	-4,913	-4,003	-3,503	-3,413	-3,359	-2,559	-2,702	-2,107	-3,621
Total Outflow	-135,036	-138,466	-131,348	-136,805	-129,062	-129,867	-134,443	-138,383	-131,802	-131,416	-133,663
Change in TDS Mass in Groundwater (in tons)											
Annual Change in Mass	-6,236	11,806	6,475	-14,939	10,801	22,261	-10,819	-11,893	-10,150	14,558	1,186
Cumulative Change in Mass	-6,236	5,569	12,044	-2,894	7,906	30,168	19,348	7,455	-2,695	11,863	

Negative numbers indicate loss or reduction

Table I-C-2 Chloride Balance for Central Basin – Baseline Period

CENTRAL BASIN GROUNDWATER CHLORIDE BALANCE											
Water Year	**2000-01**	**2001-02**	**2002-03**	**2003-04**	**2004-05**	**2005-06**	**2006-07**	**2007-08**	**2008-09**	**2009-10**	**Average**
Inflow of Chloride Mass to Groundwater (in tons)											
Spreading Grounds	12,496	16,689	14,185	11,602	10,251	17,181	14,137	10,647	9,494	14,571	13,125

mg/L - milligrams per liter

Negative numbers indicate loss or reduction

The annual TDS, chloride, and nitrate loads in No Future Projects Scenario are slightly different than the 10-year baseline average loads because the simple average (not weighted-average) baseline concentration was applied to future volumes; this is reasonable because there is no strong correlation between concentration and flow volume for each factor during the baseline period

Groundwater Quality (mg/L)	304.3	302.7	301.1	299.5	297.9	296.3	294.7	293.2	291.6	290.0	288.5	286.9	285.3	283.8	282.2	
Annual Change in Groundwater Quality from Previous Year (mg/L)	-1.6	-3.2	-4.8	-6.4	-8.0	-9.6	-11.2	-12.7	-14.3	-15.9	-17.4	-19.0	-20.5	-22.1	-23.6	

mg/L - milligrams per liter

Negative numbers indicate loss or reduction

The annual TDS, chloride, and nitrate loads in No Future Projects Scenario are slightly different than the 10-year baseline average loads because the simple average (not weighted-average) baseline concentration was applied to future volumes; this is reasonable because there is no strong correlation between concentration and flow volume for each factor during the baseline period

1 Introduction

This Appendix J describes the *Implementation Plan* that was developed by the stakeholders of the Central Basin and West Coast Basin (CBWCB or Study Area) to manage salt and nutrient (S/N) loading on a sustainable basis and ensure reliable water supplies by promoting the use of recycled water. Key components of this appendix include:

- A historical perspective on CBWCB groundwater quality,
- A description of changing conditions that could affect future groundwater quality and supply and how these factors were addressed by the CBWCB stakeholders,
- A summary of average existing and future simulated S/N groundwater quality,
- A description of existing, planned, and conceptual implementation measures, and
- A description of proposed major recycled water projects.

Section 2 presents a historical perspective on groundwater quality in the CBWCB. Section 3 describes changing conditions that could affect future groundwater quality and supply and how these factors were addressed by the CBWCB stakeholders. Section 4 summarizes average existing groundwater quality and simulated future groundwater quality for the future planning period through 2035. Section 5 assesses the need for implementation measures, which are strategies, projects, or programs established to control, reduce, or manage (mitigate) S/N loading on a sustainable basis. Section 6 presents existing, planned, and conceptual implementation measures. Section 7 describes the major recycled water projects proposed for implementation in the CBWCB. Section 8 describes the challenges that could impact achievement of recycled water and stormwater goals and objectives, as well as proposed recycled water projects and implementation measures.

References cited in this appendix and other appendices are provided at the end of the Salt and Nutrient Management Plan (SNMP). As discussed in Section 5.1 in the SNMP, total dissolved solids (TDS), chloride, and nitrate were selected as the appropriate indicator constituents of S/Ns in the Study Area.

2 Historical Perspective

In the early 1900s to late 1950s, over-pumping in the CBWCB depressed groundwater levels and caused seawater intrusion, which induced inland saline plumes containing high total dissolved solids (TDS) and chloride. In 1961 and 1965, the West Coast Basin and the Central Basin, respectively, were adjudicated and allowable pumping allocations and pumping rights were established for each of the basins. The Water Replenishment District of Southern California (WRD) was formed in 1959 to function as the basin manager to facilitate groundwater replenishment.

In the CBWCB, there are significant engineering solutions currently in place to replenish the groundwater basins and manage the seawater intrusion and other sources of S/N loading. In the Central Basin, surface spreading of imported water, stormwater, and tertiary-treated recycled water at the Montebello Forebay Spreading Grounds (MFSG) and historical spreading of stormwater at the Dominguez Gap Spreading Grounds (DGSG) replenish the groundwater basin along with other stormwater capture projects. Injection of imported water and advanced treated recycled water at the Alamitos Gap Seawater Intrusion Barrier (AGB) also prevents seawater intrusion and replenishes the groundwater basin.

In the West Coast Basin, groundwater is currently replenished by stormwater capture projects, including the DGSG. Injection of imported water and advanced treated recycled water at the Dominguez Gap Seawater Intrusion Barrier (DGB) and West Coast Basin Seawater Intrusion Barrier (WCBB) prevents seawater intrusion and replenishes the groundwater basin. Along with these replenishment projects, the Robert W. Goldsworthy (Goldsworthy) Desalter and C. Marvin Brewer (Brewer) Desalter also help to remediate brackish groundwater in the West Coast Basin, thereby reducing high TDS and chloride levels in groundwater.

3 Changing Conditions

This section describes changing conditions, including population growth, climate change, and drought, that could affect future groundwater quality and supply and how these factors were addressed by the CBWCB stakeholders as part of the SNMP.

3.1 Population Growth

According to the California Department of Finance, the State's population as a whole is projected to increase by more than 35% while Los Angeles County's population is projected to increase by approximately 18% by 2050 (USBOR, LACFCD, LACDPW, 2013). Although the population in the CBWCB is predicted to increase, use of potable supplies (imported water and groundwater) is projected to remain near 2010 levels through the end of the SNMP future planning period, i.e., 2025 (see Appendix H *Baseline and Future Water Balances* for further details). This is due to the increased use of recycled water (replacing and supplementing imported water) and overall reduced water demand due to conservation. The Study Area is mostly urbanized and essentially fully developed, so much of the predicted county-wide increase in population will likely occur through development outside the CBWCB.

3.2 Climate Change

The effects of climate change in California present many water supply challenges and unknowns. The sustainability of water supply sources will likely be impacted by warmer winter storms, reduced precipitation, winter snowpack, and surface water flows, significant dips in groundwater levels, more intense winter and spring runoff (due to precipitation occurring as rain instead of snow), and more extreme hydrologic variability between drier drought periods and wetter winter periods. Rainfall patterns locally are also likely to change with heavier rainfall periods (but reduced events) that potentially could overwhelm the flood control system, leading to less conserved stormwater, more property damage, and greater maintenance and operational demands (USBOR, LACFCD, and LACDPW, 2013). In addition, sea level along the Southern California Coast is projected to rise 5 to 25 inches above 2000 levels by 2025 due to global climate change (NRCC, 2012). Rising sea water levels have the potential to increase seawater intrusion along the coastal areas of the CBWCB.

It is noted that 7 of the last 10 seasonal years (July 1 to June 30) (2003-04, 2005-06, 2006-07, 2007-08, 2008-09, 2011-12, 2012-13) have seen below normal rainfall in Los Angeles, resulting in a lower than expected stormwater capture for recharge at the MFSG. This has led the LARWQCB to approve a longer, from 5 years to 10 years, averaging period for calculation of the relative contribution of recycled water for recharge at the MFSG (LARWQCB, 2013). Additionally, the LARWQCB increased the permitted maximum quantity of recycled water recharged at the MFSG from 35% to 45% of the total inflow from all sources (i.e., imported water, recycled water, and stormwater) in any 10-year period (LARWQCB, 2014).

In recognition of the water supply implications of greenhouse gas emissions, climate change, drought, and uncertainties and increasing costs associated with imported water supplies, the CBWCB stakeholders have been planning and implementing projects to maximize the use of recycled water and stormwater, encourage conservation, and address seawater level rise. Thus, consideration of climate change was a key factor in the development of projects and implementation measures (see Section 10) to reduce reliance on expensive, energy-intensive (due to pumping, distribution, and other costs), and increasingly unreliable imported water supplies by replacing these supplies with drought-proof, reliable, safe, and sustainable recycled water at the MFSG, seawater intrusion barriers, and for irrigation. Various measures and studies to increase stormwater capture have also been implemented and planned, including low impact development (LID) projects, new retention basins, rubber dams along the San Gabriel River, increasing the height of water storage behind the Whittier Narrows Dam, and the MFSG interconnection pipeline, among others. It is anticipated that projects and programs associated with the MS4 Permit will also result in increased stormwater capture.

As recognized in the Department of Water Resources (DWR) Public Review Draft of the Water Plan Update 2013 (DWR, 2013), conservation is a fundamental component of the South Coast region's water management planning. The South Coast Region includes all of Orange County and portions of Ventura, Los Angeles (including the CBWCB), San Bernardino, Riverside, and Sana Diego counties. Water agencies in the South Coast have been aggressively implementing water conservation since the 1990s. The GLAC IRWMP (GLAC IRWMP Leadership Committee, 2014) has been developed to define a clear vision and direction for the sustainable management of water resources in the GLAC Region for the next 20 years.

The Water Conservation Act of 2009 (Senate Bill [SB] x7-7) requires each urban retail agency to establish in its Urban Water Management Plan (UWMP) a reduction goal to help California achieve a 20% statewide reduction in daily per capita water use by 2020. The UWMPs indicate the South Coast Hydrologic Region had a population-weighted baseline average water use of 188 gallons per capita per day with an average population-weighted 2020 target of 159 gallons per capita per day. In addition, although the population in the CBWCB is predicted to increase, conservation programs are helping to maintain the use of potable supplies (imported water and groundwater) near 2010 levels through the end of the SNMP future planning period, i.e., 2025.

3.3 Drought

Historically, California has experienced frequent periods of prolonged drought. Based on scientific projections, drought is expected to occur more frequently and for longer intervals due to climate change. With significant below-normal rainfall since 2012, the current drought is being described as the driest period in the State's recorded history. There was less rain in 2013 than in any year since California became a state in 1850. Locally, there has been approximately 5.6 inches of rain since October 1, 2013 (when the "water year" starts from a record-keeping standpoint), approximately 37% of the normal precipitation for this period. A Sierra Mountain snow survey conducted by the DWR at the end of February and March 2014 found the snowpack's statewide water content at about 25% of average. According to the United States Drought Monitor, a majority of the State is designated in either Exceptional Drought (including the CBWCB) or Extreme Drought (http://droughtmonitor.unl.edu/Home/StateDroughtMonitor.aspx?CA).

The current drought, as a result of the lack of precipitation, has impacted the following areas, which has affected imported water and groundwater supplies in the CBWCB:

- San Gabriel Mountains and Valley which feed runoff to rivers leading to recharge at the Montebello Forebay Spreading Grounds;
- Sierra Nevada Mountains which feed the Owens River, the Los Angeles Aqueduct, Northern California, the Sacramento-San Joaquin River Delta, and the California Aqueduct;
- Western United States and the Rocky Mountains which feed the Colorado River; and
- Groundwater – In the Montebello Forebay, which supplies many production wells and also serves as the conduit to supply groundwater to "downstream" areas of the Central Basin and West Coast Basin, groundwater levels have fallen over 50 feet since 2011 due to the extended drought. Water levels have dropped to their lowest levels in over 35 years, causing some production wells to have lowered pumps to keep up with the decline.

Due to seriously diminished water supplies in the State, on January 17, 2014, Governor Jerry Brown declared a State of Emergency (Proclamation No. 1-17-2014, http://www.gov.ca.gov/news.php?id=18368). As part of his proclamation, the Governor directed State officials to take all necessary actions to prepare for drought conditions. On April 25, 2014, Governor Brown issued an Executive Order (Proclamation No. 4-25-2014, http://gov.ca.gov/news.php?id=18496) declaring a continued state of emergency due to severe drought conditions, with an emphasis on statewide conservation and included directives to strengthen the State's ability to manage water effectively under drought conditions. Directive No. 10 in the Executive Order states, "The Water Board [SWRCB] will adopt statewide general waste discharge requirements to facilitate the use of treated wastewater that meets standards set by the Department of Public Health, in order to reduce demand on potable water supplies." (Office of California Governor Edmund G. Brown, Jr., 2014b).

In direct response to the Governor's April 2014 Executive Order, the SWRCB adopted *General Waste Discharge Requirements for Recycled Water Use* (General Order No. WQ 2014-0090-DWQ; http://www.waterboards.ca.gov/board_decisions/adopted_orders/water_quality/2014/wqo2014_0090_dwq_revised.pdf) on June 3, 2014 to streamline permitting for recycled water use (i.e., relieve producers, distributors, and users of recycled water from the lengthy permit approval process) throughout the State. This General Order is intended to increase local water supplies by promoting the non-potable use of recycled water in communities grappling with drought conditions. Additionally, the General Order is consistent with the Recycled Water Policy that was adopted by the SWRCB in 2009 and amended in 2013, which required the development of SNMPs for all groundwater basins in California. Thus, all uses of recycled water allowed by the General Order must be consistent with the SNMPs that will be approved by the Regional Water Quality Control Boards. Importantly, the General Order did not modify existing permitted recycled water quality limits established for irrigation. If this was the case, this would have significantly limited the sustainable and cost effective use of recycled water to offset demand for raw and potable water supplies in the CBWCB.

Currently, permitted recycled water quality limits established for non-potable reuse (irrigation, industrial and recreational activities) are generally more conservative than the SMCLs established for TDS and chloride. As part of the SNMP, the CBWCB stakeholders, in close consultation with the LARWQCB, modeled the impacts on groundwater quality from the increased use of recycled water for irrigation at the SMCLs/MCL for S/Ns. As discussed further in Section 7.4.1, the modeling results showed that there were minimal potential impacts to the basins when utilizing recycled water for irrigation at these generally higher concentrations, even at increased volumes. Therefore, the CBWCB stakeholders believe that modification of existing permit levels for recycled water for non-potable reuse are warranted to further reduce dependency on potable water supplies, meet the goals set forth in the Recycled Water Policy to increase the use of recycled water (as discussed in Section 1.2), and more fully embrace the spirit of the Governor's drought proclamations.

In addition to the modification of existing permit levels for recycled water for non-potable reuse, the CBWCB stakeholders have proposed other recycled water projects (refer to Section 10.1 and Appendix J) for implementation in the basins. As discussed further in Section 7 and Appendix I, impacts to groundwater quality from the proposed recycled water projects were estimated using the mixing model that was developed as part of the SNMP. The SNMP modeling results clearly demonstrate that future recycled water projects that may increase S/N loading are more than offset by projects that reduce S/N loading and thus, groundwater quality overall in the CBWCB is either improving or remaining well below BPOs, for S/Ns. Since some of the proposed recycled water projects in the CBWCB actually reduce S/N loading or improve groundwater quality, they were also identified as implementation measures, as discussed further in Section 10.2 and Appendix J. Thus, the proposed recycled water projects and implementation measures developed by the CBWCB stakeholders directly address the impacts of drought, while improving or maintaining high-quality groundwater in the basins.

Recognizing the implications of changing climatic conditions, WRD and SNMP stakeholders have developed a number of plans and programs to reduce reliance on imported water by increasing use of stormwater and recycled water. WRD has developed the Water Independence Now (WIN) program, which is a series of projects that will fully utilize stormwater and recycled water sources to restore and protect the groundwater resources. WIN seeks to completely eliminate dependence on imported water to ensure the future security of the CBWCB by developing local resources to create a locally sustainable groundwater supply.

To complement the WIN program, WRD and CBWCB stakeholders have developed the GBMP (CH2MHILL, 2012b) to identify and assess impacts of potential projects and programs to enhance basin replenishment, increase the reliability of groundwater resources, improve and protect groundwater quality, and ensure that the groundwater supplies are suitable for beneficial uses. This GBMP identifies opportunities to develop supplemental replenishment water supplies to further utilize the CBWCB. The key objective for creating additional replenishment water supply is to significantly reduce imported water use by providing for increased pumping from the CBWCB. Various scenarios and alternatives were developed and evaluated with the updated USGS MODFLOW groundwater flow model with the goal of maximizing the development of groundwater supplies.

3.4 Greenhouse Gas Emissions

Greenhouse gases, measured and evaluated in terms of carbon dioxide, are generated from the combustion of carbon-based fuels, principally wood, coal, oil, and natural gas. Greenhouse gas emissions are known to cause climate change at various scales, including local and regional. The amount of energy associated with various water sources depends on many factors, including the quality of the source water, the energy required for water treatment, the efficiency of conveyance and distribution systems, and the distance to approved end uses. In the CBWCB, recycled water and groundwater require significantly less distance for transport to approved end uses compared with imported supplies, and thus results in substantial overall energy savings, mainly due to delivery.

From an energy standpoint, greater reliance on water conservation, recycled water, and stormwater provides significant energy benefits compared with imported water. These energy benefits provide significant reductions in greenhouse gas emissions in direct relation to their energy savings.

The CBWCB stakeholders have recognized the importance of reducing greenhouse gas emissions. For over 50 years, recycled water and stormwater have been used in the Montebello Forebay for groundwater recharge, thus reducing reliance on more energy-intensive imported water supplies. Water conservation programs are currently in place (thus, conservation was identified as an implementation measure; see Appendix J), which not only conserve energy but may also result in reduced S/N loading, thus improving groundwater quality. To further meet the goals of the Recycled Water Policy and the Governor's drought proclamation, multiple projects have been proposed by the CBWCB stakeholders to increase the use of recycled water (replacing and supplementing more energy-intensive imported water supplies), as further discussed in Section 10.2. The use of recycled water in the CBWCB has been proven to be an energy-efficient, safe, and reliable resource and has played a vital role in increasing the sustainability of the overall water supply. Impacts to air quality, including greenhouse gas emissions, will be evaluated as part of the CEQA process for the individual projects in the basins and was also assessed for the program alternatives presented in the SED.

4 Summary of Groundwater Quality Assessment and Results

Average existing water quality and assimilative capacity results and the methodology for determining the average groundwater quality are presented in Appendix G *Hydrogeologic Conceptual Model and Existing Salt and Nutrient Groundwater Quality.* Appendix I *Simulated Baseline and Future Salt and Nutrient Groundwater Quality* presents simulated baseline (Water Year [WY] 2000-01 to 2009-10) and future (WY 2010-11 to 2024-25) groundwater quality and assimilative capacity and the methods used to predict water quality. Results are summarized here for context.

Comparison of average existing and estimated future groundwater quality with the BPO for nitrate and Basin-Specific Basin Plan Objectives (BSBPOs)[1] for TDS and chloride and assessment of water quality trends informs the need for, or lack of need for implementation measures. This section summarizes existing groundwater quality and available assimilative capacity and estimated future groundwater quality and assimilative capacity at the end of the SNMP future planning period in 2025. Water quality trends are also discussed.

4.1 Existing Groundwater Quality and Assimilative Capacity

The CBWCB, Central Basin subareas, and adjacent basins are shown in Figure 2[2]. Groundwater quality was assessed with and without inclusion of the coastal areas shown in Figure 2 for the following reasons: 1) high salinity of the coastal areas are associated with historical seawater intrusion, 2) the location of these areas near the coast and in some areas seaward of the seawater intrusion barriers, and 3) the likelihood that these areas will not be used for potable supply[3]. The West Coast Basin water quality was further assessed with and without the large trapped WCBB-inland saline plume, shown in green in Figure 2.

Table J-1 and Figure 40 present the average existing TDS, chloride, and nitrate as nitrogen (nitrate-N) concentrations for each Central Basin subarea and for the basins as a whole and each constituent's BPO/BSBPOs. The calculated available existing assimilative capacity for each area is also presented in Table J-1.

The analysis indicates that average TDS, chloride, and nitrate concentrations in the Central Basin are below BPO/BSBPOs and assimilative capacity is available. The elevated average TDS

[1] The Central Basin and West Coast Basin have different BSBPOs for TDS and chloride. The have the same BPO for nitrate.

[2] The subareas shown on Figure 2 represent model subareas. Due to gridding of the model domain, the subarea boundaries have a stepped rather than a smooth appearance.

[3] Based on groundwater quality, large portions of the coastal areas are not suitable for potable supply in accordance with SWRCB Sources of Drinking Water Policy (Resolution No. 88-63 as revised by Resolution No. 2006-0008).

Table J-1 Summary of Existing Average Groundwater Quality and Available Assimilative Capacity

TDS - total dissolved solids
Cl - chloride
NO_3-N - nitrate as nitrogen
NA - not applicable; no Model Layer 1 in these areas
Averages based on groundwater concentration contour maps; average of all layers is a weighted average based on area and aquifer thickness
Negative numbers indicate there is no available assimilative capacity
BPO/BSBPO - Basin Plan Objective or Basin Specific Basin Plan Objective
- Average concentration indicated exceeds BPO
- Model Layer 1 not included; typically unsaturated within the Los Angeles Forebay and of very limited extent Whittier Area (see explanation in Appendix G *Hydrogeologic Conceptual Model and Existing Salt and Nutrient Groundwater Quality* Section 2.6.3)

a - Includes both Central Basin and West Coast Basin

b - Elevated TDS and chloride concentrations in the Whittier Area are likely naturally occurring as discussed in Appendix G *Hydrogeologic Conceptual Model and Existing Salt and Nutrient Groundwater Quality* Section 3.5.3

concentration in the Whittier Area (see Table J-1) is due to naturally-occurring conditions, specifically dissolution of formation materials high in silts and clays and/or of marine origin.

Due to historical seawater intrusion in the West Coast Basin, average TDS and chloride concentrations exceed BPO/BSBPOs when the WCBB-inland saline plume is included and, as a result, there is no available assimilative capacity for TDS and chloride in this basin. However, average nitrate concentrations in the West Coast Basin are well below the BPO and assimilative capacity is available for nitrate. As shown in Figure 40 and Table J-1, when the WCBB-inland saline plume[4] is removed from the basin average calculations, the West Coast Basin does have available assimilative capacity for TDS, chloride, and nitrate.

It is important to note that, despite the existing elevated TDS and chloride groundwater concentrations in the West Coast Basin, TDS and chloride concentrations are declining due to existing and proposed implementation measures. Existing implementation measures include the basin adjudication and associated limits on pumping, the seawater intrusion barriers, and the desalters. TDS and chloride concentrations will continue to decline and the decline will accelerate with the proposed increased use of recycled water that has received advanced water treatment (AWT) at the seawater barriers (completely replacing imported water) combined with the proposed increased pump and treat by the desalters (including expansion of the Goldsworthy Desalter).

4.2 Future Groundwater Quality and Assimilative Capacity

Future groundwater quality was simulated for each of the basins and basin subareas/model layers assuming implementation of planned projects through the future planning period (WY 2010-11 to 2024-25). Future projects and simulated water quality results are presented in Appendix I *Simulated Baseline and Future Salt and Nutrient Groundwater*. Major future projects or "scenarios" simulated by the SNMP mixing model and discussed in Appendix I are summarized in **Table J-2**.

Table J-3 lists the change in groundwater quality calculated for the Central Basin and West Coast Basin for each of the future project scenarios described above.

In the Central Basin for all projects, TDS, chloride, and nitrate concentrations increase slightly in groundwater, but eventually level out as 2025 is approached. The increase in nitrate levels in groundwater is very small and nitrate is not considered a water quality concern because concentrations remain well below the BPO. TDS, chloride, and nitrate do not exceed BPO/BSBPOs by 2025 in the Central Basin. The implementation of either Groundwater Reliability Improvement Program (GRIP) Recycled Water Project A (GRIP A) or Recycled Water Project B (GRIP B) (Scenarios 6 and 7, respectively) would result in TDS and chloride concentrations in groundwater to remain below BPO/BSBPOs. The GRIP B Scenario (all tertiary-

---

[4] The saline plume that is inland of the West Coast Basin Barrier was able to be removed when calculating existing salt and nutrient concentrations overall in the basin, but it was not possible to remove the plume area for future (planning period through 2025) groundwater quality simulations due to difficulties in extracting water balances for this subarea from the groundwater model.

Table J-2 List of Scenarios Simulated by the SNMP Mixing Model

Scenario No.	Description
1	**No Future Projects** – Average of baseline period conditions (i.e. continuation of only existing projects and no implementation of proposed projects) reproduced for each year of the future planning period (Water Year [WY] 2010-11 through 2024-25).
2	**Increased Recycled Water for Irrigation (Baseline Period Average Water Quality)** – This is a proposed project in the Central Basin and West Coast Basin (CBWCB) that would increase the use of recycled water for irrigation (replacing imported water and groundwater). Recycled water used for irrigation is anticipated to increase from the 10-year baseline period (WY 2000-01 through 2024-25) average of about 10,600 acre-feet per year (AFY) to about 23,100 AFY by WY 2024-25. For this scenario, recycled water quality for salt and nutrients (S/Ns) is equivalent to the baseline period average (see Table I-9 in Appendix I). For the CBWCB Salt and Nutrient Management Plan (SNMP), S/Ns specifically refers to nitrate as nitrogen (nitrate-N), total dissolved solids (TDS), and chloride.
3	**Increased Recycled Water for Irrigation (Water Quality Equivalent to MCL/SMCLs)** – This is a proposed project in the CBWCB that would increase the use of recycled water for irrigation (replacing imported water and groundwater). Recycled water used for irrigation is anticipated to increase from a baseline period average of about 10,600 AFY to about 23,100 AFY by WY 2024-25. For this scenario, recycled water quality is equivalent to: • Nitrate as nitrogen (nitrate-N) – Primary Maximum Contaminant Level (MCL) of 10 milligrams per liter (mg/L), • TDS – Secondary Maximum Contaminant Level (SMCL) of 1,000 mg/L, and • Chloride – SMCL of 500 mg/L. These recycled water concentrations are higher than the baseline period averages (Scenario 2). Currently, permitted recycled water quality limits established for non-potable reuse (irrigation, industrial and recreational activities) are generally more conservative than the SMCLs established for TDS and chloride.
4	**Seawater Intrusion Barriers** – This scenario consists of planned projects that would increase injection volumes and increase the use of recycled water that has undergone advanced water treatment (AWT) to completely replace imported water at the West Coast Basin Seawater Intrusion Barrier (WCBB), Alamitos Gap Seawater Intrusion Barrier (AGB), and Dominguez Gap Seawater Intrusion Barrier (DGB). Total AWT recycled water used for injection at the barriers is anticipated to increase from a baseline period average of about 9,500 AFY to about 31,700 AFY by WY 2018-19. The switch to AWT recycled water from imported water significantly reduces TDS and chloride in the recharge water (changes in nitrate concentrations are not significant). As a result, these planned seawater barrier projects were designated as an implementation measure, as further discussed in Section 6.2.2 of this appendix.

Scenario No.	Description
5	**Increased Groundwater Pump and Treat by the Desalters in the West Coast Basin** – This scenario consists of planned projects that would increase the amount of groundwater pumped and treated by the two existing desalter facilities in the West Coast Basin. The Robert W. Goldsworthy Desalter will be expanded and the associated groundwater pumping will increase from a baseline period average of about 1,900 AFY to about 5,500 AFY by WY 2014-15. Groundwater pumping for treatment by the C. Marvin Brewer Desalter is also expected to increase from a baseline period average of about 500 AFY to an average of about 900 AFY in the future planning period. Since these planned desalter projects are expected to improve groundwater quality, they were designated as an implementation measure, as further discussed in Section 6.2.2 of this appendix.
6	**Groundwater Reliability Improvement Program, Recycled Water Project A (GRIP A)** – This is a planned project in the Central Basin that would increase the use of recycled water, specifically a combination of AWT recycled water (10,000 acre-feet per year [AFY]) and tertiary-treated recycled water (11,000 AFY) to completely replace imported water for recharge at the Montebello Forebay Spreading Grounds (MFSG) beginning WY 2017-18.
7	**GRIP Recycled Water Project B (GRIP B)** – This is a proposed project in the Central Basin that would increase the use of tertiary-treated recycled water (21,000 AFY) to completely replace imported water for recharge at the MFSG beginning WY 2014-15.
8	**Combined Projects/Scenarios** – A combination of Scenarios 2 (increased recycled water for irrigation at baseline period average S/N concentrations), 4, 5, 6 (GRIP A), and minor future changes (includes increased and decreased imported water for supply in the West Coast Basin and Central Basin, respectively, and increased stormwater capture).
9	**Combined Projects/Scenarios** – A combination of Scenarios 2 (increased recycled water for irrigation at baseline period average S/N concentrations), 4, 5, 7 (GRIP B), and minor future changes (includes increased and decreased imported water for supply in the West Coast Basin and Central Basin, respectively, and increased stormwater capture).
10	**Combined Projects/Scenarios** – A combination of Scenarios 3 (increased recycled water for irrigation at SMCLs/MCL), 4, 5, 6 (GRIP A), and minor future changes (includes increased and decreased imported water for supply in the West Coast Basin and Central Basin, respectively, and increased stormwater capture).
11	**Combined Projects/Scenarios** – A combination of Scenarios 3 (increased recycled water for irrigation at SMCLs/MCL), 4, 5, 7 (GRIP B), and minor future changes (includes increased and decreased imported water for supply in the West Coast Basin and Central Basin, respectively, and increased stormwater capture).

SNMP – Salt and Nutrient Management Plan
S/N – salt and nutrient
MCL – Maximum Contaminant Level
SMCL – Secondary Maximum Contaminant Level
Nitrate-N – nitrate as nitrogen
TDS – total dissolved solids
mg/L – milligrams per liter
CBWCB – Central Basin and West Coast Basin
AFY – acre-feet per year
WY – Water Year
GRIP – Groundwater Reliability Improvement Program
GRIP A – GRIP Recycled Water Project A
GRIP B – GRIP Recycled Water Project B
MFSG – Montebello Forebay Spreading Grounds

TDS - total dissolved solids
AWT - advanced water treatment
MCL - maximum contaminant level
Cl - chloride
SMCL - secondary MCL
NO_3-N - nitrate as nitrogen
mg/L - milligrams per liter
NC - No assimilative capacity available
A.C. - assimilative capacity
GRIP - Groundwater Reliability Improvement Program
GRIP A – GRIP Recycled Water Project A
GRIP B - GRIP Recycled Water Project B
RW - recycled water
Baseline - The period of time from water year 2000-01 to 2009-10 used for assessment of salt and nutrient inflows and outflows

a - "Overall Scenario" quantifies the impacts of the indicated future project/scenario in combination with existing projects in the CBWCB, i.e. including average baseline conditions (No Future Projects Scenario) continued through the future planning period

b - "Scenario minus Baseline Conditions" quantifies the impacts of the indicated future project/scenario solely, without existing projects in the CBWCB, i.e. excluding average baseline conditions (No Future Projects Scenario) or background loading

c - Positive value indicates the scenario is increasing concentrations or using additional available assimilative capacity; negative value indicates the scenario is improving groundwater quality or increasing available assimilative capacity

d -Minor Future Changes, as referenced for all combined scenarios (8, 9, 10, and 11), include decreased imported water use for supply in the Central Basin, slightly increased imported water for supply in the West Coast Basin, and increased stormwater capture at the DGSG and other facilities

e - 2010 year values used to calculate changes in concentrations and use of assimilative capacity are the average existing groundwater quality and available assimilative capacity treated recycled water) would increase TDS, chloride, and nitrate concentrations relative to baseline conditions (i.e. Scenario 1, No Future Projects) and the GRIP A Scenario (blend of tertiary-treated and AWT recycled water) results are similar to the No Future Projects Scenario.

In the West Coast Basin for all projects, TDS and chloride concentrations are decreasing, and nitrate concentrations are very slightly increasing in groundwater. As with findings in the Central Basin, the increase in nitrate concentrations in the West Coast Basin is minimal and thus, nitrate is not considered a water quality concern because concentrations remain significantly below the BPO. Existing average TDS and chloride concentrations are above BSBPOs due to historical seawater intrusion. Existing implementation measures such as basin adjudication, injection at the seawater intrusion barriers, and operation of the desalters will continue to improve TDS and chloride groundwater quality over time. Planned implementation measures will further improve groundwater quality over time. Average TDS and chloride concentrations are expected to decline in the West Coast Basin through 2025 and are estimated to achieve BSBPOs by about 2035.

Nitrate concentrations in groundwater in the CBWCB are well below the BPO with very minor increasing trends. Accordingly, nitrate is not currently or predicted to be a groundwater quality concern in the future in the CBWCB and thus, nitrate did not drive implementation measures development. The increased recycled water irrigation scenarios (Scenarios 2 and 3) both slightly increase TDS and chloride loading, with greater loading from Scenario 3 due to concentrations at SMCLs/MCL, which are higher than the baseline period averages. Nonetheless, S/N concentrations in groundwater remain below the BPO/BSBPOs in the Central Basin. When Scenarios 2 and 3 are combined with existing and proposed implementation measures (see Section 6.2), S/N concentrations decline over time in the West Coast Basin.

Because the negative water quality impacts of increased recycled water use for irrigation have been demonstrated in the SNMP to be minor and more than offset by implementation measures and projects that improve groundwater quality, the SNMP may be used to modify currently permitted recycled water quality limits established for non-potable reuse (irrigation, industrial and recreational activities) and provide a basis for streamlining the permitting process for future recycled water projects, per the Recycled Water Policy and the Governor's recent drought proclamations (refer to Section 3.3). In particular, irrigation with recycled water has very minor impacts on groundwater quality and thus, permits for individual irrigation sites do not appear warranted. As a result, TDS, chloride, and nitrate limits for recycled water used for irrigation and other non-potable reuse applications can be set equivalent to SMCLs/MCL, while still protecting groundwater quality and preserving beneficial uses.

5 Assessment of Need for Implementation Measures

The Recycled Water Policy states that within one year of the receipt of a proposed SNMP, the Regional Water Quality Control Board shall consider for adoption revised implementation plans, consistent with Water Code section 13242, for those groundwater basins where Water Quality Objectives (WQOs) or BPOs for S/Ns are being, or are threatening to be exceeded. Accordingly, the need for, or lack of need for implementation measures was determined by comparing existing and projected future groundwater quality with respect to BPO/BSBPOs.

Nitrate does not exceed or threaten to exceed its BPO in either the Central Basin or West Coast Basin. TDS and chloride do not exceed or threaten to exceed their BSBPOs in the Central Basin. In the West Coast Basin, average TDS and chloride concentrations in groundwater currently exceed BSBPOs due to historical seawater intrusion, but are declining and expected to reach BSBPOs in the future (approximately 2035) as a result of existing and planned implementation measures. Thus, in accordance with the Recycled Water Policy, implementation measures are warranted for the West Coast Basin. While not strictly required by the Recycled Water Policy, implementation measures have also been developed for the Central Basin. All implementation measures developed by the stakeholders for the CBWCB are described in Section 6.

Elevated average TDS and chloride concentrations in groundwater in the West Coast Basin are the result of seawater intrusion in areas along the coast caused by significant historical groundwater over-pumping and associated drawdown. A large plume of saline groundwater became trapped inland after operation of the WCBB. This WCBB-inland saline plume causes overall average TDS and chloride concentrations to exceed BSBPOs in the West Coast Basin. This is due to the significant size of the WCBB-inland saline plume and the high TDS and chloride concentrations within the plume. WRD has estimated the volume of the WCBB-inland saline plume to be greater than 600,000 acre-feet (AF) (Johnson, 2013).

Significant implementation measures have been undertaken and are planned to protect groundwater quality in the CBWCB and to restore West Coast Basin groundwater quality to below BSBPOs. In order to address over-pumping, the Central Basin and West Coast Basin were adjudicated in 1965 and 1961, respectively, to limit groundwater pumping and WRD was formed in 1959 to manage the basins and facilitate groundwater recharge. WRD and other stakeholders have addressed the seawater intrusion by optimizing operation of the WCBB, DGB, and AGB; using high quality water for injection in the barriers, which replenishes the basins and dilutes the saline groundwater; operating the Brewer Desalter and Goldsworthy Desalter to extract brackish groundwater from the leading edge of the WCBB-inland saline plume and in the future from targeted spots within the plume; surface spreading of stormwater to dilute groundwater salt concentrations; and operating the MFSG to replenish the Central Basin. Expansion of the Goldsworthy Desalter and increased recharge at the WCBB, DGB, AGB, DGSG, and MFSG are currently planned to further mitigate the effects of basin overdraft, including seawater intrusion. Over the past 20 years, WRD has evaluated other alternatives to remediate the saline groundwater. These projects are hindered by legal, technical, economic, and institutional obstacles such as:

- Adjudicated pumping rights that limit groundwater extraction to 64,468 AFY in the West Coast Basin and 217,367 AFY in the Central Basin;
- Impacts of increased desalter well pumping on the seawater intrusion barriers that necessitate additional barrier injection wells and replenishment water;
- Capital and operation costs for extraction and injection wells, membrane treatment for saline groundwater, brine disposal systems, piping systems, etc.; and

- Lack of open space for new wells, treatment systems, and pipelines.

The analysis presented in Appendix I *Simulated Baseline and Future Salt and Nutrient Groundwater Quality* of the SNMP demonstrate that for the West Coast Basin, the existing and planned implementation measures are improving groundwater quality. Specifically, average TDS and chloride concentrations are expected to decline in the West Coast Basin through 2025 and are estimated to achieve BSBPOs in about 2035.

Based on the SNMP analysis, no additional implementation measures beyond what has been implemented and are planned through 2025 are warranted. Nonetheless, the S/N management process in the CBWCB is active and ongoing. S/N groundwater quality will continue to be monitored through the future to determine if water quality improvement objectives are met and the need for additional implementation measures will be reassessed when the SNMP is updated in 10 years or when deemed necessary based on the results of the SNMP Monitoring Program.

6 Implementation Measures

6.1 Types of Impacts – Loading Versus Concentration

Implementation measures are projects or programs established to control, reduce, or manage (mitigate) S/N loading on a sustainable basis. Implementation measures can impact the groundwater basins in two ways: 1) they can decrease the S/N loading, and/or 2) they can decrease the concentration of S/Ns in groundwater. This distinction is important in understanding the different types of benefits of implementation measures in the context of S/N management. The impacts are differentiated by the source water quality and whether one source water replaces another of different water quality. Some of the proposed major recycled water projects discussed in Section 7 do not decrease S/N loading or decrease S/N concentrations in groundwater and hence, they were not designated as implementation measures.

Table J-4 shows the range in average TDS, chloride, and nitrate-N concentrations in different water sources recharged in the CBWCB. The different water sources are listed from top to bottom, from lowest to highest relative TDS concentrations. The current average groundwater concentrations in the Central Basin and the West Coast Basin are also included in the table.

The average water quality values shown in Table J-4 may be used to generally illustrate the loading and concentration impacts on a groundwater basin from the different source waters. Depending on the concentration of a constituent in a source water, and whether or not this source water is replacing another source water, a project can increase or decrease the S/N loading into a basin while also decreasing the S/N concentration in groundwater. Figure 63 shows a schematic diagram representing how several types of projects impact the basins differently in terms of TDS loading and average TDS concentrations in groundwater.

Table J-4 Average TDS, Chloride and Nitrate Source Water Concentrations

Type of Water	TDS [a] (mg/L)	Chloride [a] (mg/L)	NO_3–N [a] (mg/L)
AWT RW [b]	65 - 98	9 - 37	0.26 - 1.13

WTP – Water Treatment Plant
WRF – Water Recycling Facility
WRP – Water Reclamation Plant
AWTF – Advanced Water Treatment Facility
WY – water year
TIWRP – Terminal Island Water Reclamation Plant/Advanced Water Purification Facility
WRD – Water Replenishment District of Southern California
MFSG – Montebello Forebay Spreading Grounds
MWD – Metropolitan Water District of Southern California
WBMWD – West Basin Municipal Water District
SDLAC – Sanitation Districts of Los Angeles County

a – Water quality information is presented in Appendix I *Simulated Baseline and Future Salt and Nutrient Groundwater Quality;* concentrations are expressed as ranges of averages from different source waters over the 10-year baseline period from WY 2000-01 to 2009-10 (e.g., the “AWT RW” ranges are made up of the 10-year averages for constituents from the three different AWT facilities)

b – AWT RW from WBMWD’s Edward C. Little WRF, WRD’s Leo J. Vander Lans AWTF, and City of Los Angeles’ TIWRP

c – Montebello Forebay Spreading Grounds intake during storm events and Los Angeles County’s stormwater monitoring station S10 near the Dominguez Gap Spreading Grounds

d – Based on MWD’s Jensen WTP, Diemer WTP, Weymouth WTP, and City of Los Angeles’ WTPs

e – Combination of imported water, stormwater, and recycled water

f – Untreated water from the Colorado River and the State Water Project

g – Tertiary-treated RW from SDLAC’s Pomona, San Jose Creek, and Whittier Narrows WRPs

h – Tertiary-treated RW from SDLAC’s San Jose Creek, Los Coyotes, and Long Beach WRPs, and WBMWD’s Edward C. Little WRF

i – Averages excluding coastal areas

For example, the first two arrows on the left in Figure 63 could represent the Scenario 4 (see Section 4.2), which replaces imported water (higher TDS concentration) with AWT recycled water (lower TDS concentration) at the three seawater intrusion barriers. In this case, both the TDS loading and average TDS concentration in groundwater decrease. However, if a source water containing a lower TDS concentration than those in ambient groundwater is added to the basin without replacing another source water (e.g., new stormwater capture project or a new AWT recycled water injection well), the TDS loading would increase while the basin concentration would decrease. This is represented by the third arrow from the left in Figure 63. Another example is the desalter wells. These wells extract impacted groundwater within the WCBB-inland saline plume for treatment, resulting in increased outflow of TDS (decreased loading) and decreased TDS concentrations in groundwater, illustrated by the second arrow from the right in Figure 63. The two types of impacts (S/N loading and concentration) were assessed for various implementation measures and proposed major recycled water projects in the CBWCB.

Examples of project impacts depicted in Figure 63 are summarized in **Table J-5**.

6.2 Existing, Planned, and Conceptual Implementation Measures

Implementation measures are projects, programs, or strategies for stakeholders to manage S/Ns on a sustainable basis. "Sustainable" in this context means using a resource such that the resource is not depleted or permanently damaged. The SNMP planning horizon is 2025 for the implementation measures that were developed by the CBWCB stakeholders and summarized in this section. The implementation measures were classified into three categories: existing, planned, and conceptual.

Table J-6 lists the existing, planned and conceptual implementation measures, as well their impacts to groundwater in terms of S/N loading and concentration. Existing implementation measures are projects/programs that are currently in place. For existing implementation measures, the impacts to S/N loading and concentrations in groundwater are determined in relation to conditions before they were implemented (e.g., existing seawater intrusion barriers currently recharged with AWT recycled water and imported water are compared to seawater intrusion barriers prior to the injection of AWT recycled water, when only imported water was injected). Implementation measures are classified as planned if they are scheduled to be in operation prior to 2025, notwithstanding exigencies that are outside the control of the project sponsors. Available costs are shown for planned implementation measures. The conceptual implementation measures are projects that have been hypothetically identified, so they may or may not be implemented before or after 2025, if ever.

Some of the implementation measures listed in Table J-6, specifically major existing and proposed projects in the basins, were quantitatively assessed for their S/N groundwater quality impacts using the SNMP mixing model, as discussed further in Section 4.2. The remaining implementation measures were not modeled because these projects were smaller in size and complexity (thus, their impacts to overall groundwater quality were insignificant) and/or lacked details that were required to perform modeling (e.g. conceptual implementation measures).

Table J-5 Examples of Projects Affecting Salt and Nutrient Loading and Concentrations in Groundwater

Description	Impact to S/N Loading to Groundwater	Impact to S/N Concentrations in Groundwater	Example Project
Replace current water with lower TDS water	Decrease	Decrease	Seawater intrusion barriers replacing imported water with AWT recycled water
Add lower TDS water	Increase	Decrease	New stormwater capture project; new AWT recycled water injection wells [a]
Replace current water with higher TDS water	Increase	Increase	Existing irrigation that replaces imported water with tertiary-treated recycled water
Add higher TDS water	Increase	Increase	New irrigation with tertiary treated recycled water
Increase saline plume pumping	Decrease	Decrease	Desalters
Increase well pumping	Decrease	None	Typical groundwater production

TDS – total dissolved solids AWT – advanced water treatment S/N – salt and nutrient

a – New injection of AWT recycled water via wells (not replacing an existing water source) is currently a conceptual implementation measure

Table J-6 CBWCB Implementation Measures

Timeframe	Category	Implementation Measure (IM) No.	Description of Existing S/N Management Strategy	Basin	Cost [a]	Implementation Date	Impact to S/N Loading to Groundwater	Impact to S/N Concentrations in Groundwater
Existing	Seawater intrusion control	1	Three seawater intrusion barriers (WCBB, DGB, and AGB), existing operations with imported water and AWT recycled water	CBWCB	N/A	Existing	Decrease	Decrease
		2	Two desalters (Brewer Desalter and Goldsworthy Desalter)	WCB	N/A	Existing	Decrease	Decrease
	Groundwater recharge	3	Dominguez Gap Spreading Grounds existing operations	WCB	N/A	Existing	Increase	Decrease
		4	Montebello Forebay Spreading Grounds existing operations	CB	N/A	Existing	Increase	Decrease
		5	Montebello Forebay Spreading Grounds interconnection pipeline	CB	N/A	Existing	Increase	Decrease

CBWCB – Central Basin and West Coast Basin; CB – Central Basin; WCB – West Coast Basin; S/N – salt and nutrient; SNMP – Salt and Nutrient Management Plan
SW – stormwater; BMPs – best management practices; WRP – Water Reclamation Plant; LID – low impact development; TMDL – total maximum daily load
DGB – Dominguez Gap Seawater Intrusion Barrier; AGB – Alamitos Gap Seawater Intrusion Barrier; WCBB – West Coast Basin Seawater Intrusion Barrier; N/A – Not available
AWT – advanced water treatment; NPDES – National Pollutant Discharge Elimination System; MS4 – Municipal Separate Storm Sewer System
LARWQCB – Los Angeles Regional Water Quality Control Board; MWD – Metropolitan Water District of Southern California; WRD – Water Replenishment District of Southern California
LACDPW – Los Angeles County Department of Public Works; CDPH – California Department of Public Health; GLAC IRWMP – Greater Los Angeles County Integrated Regional Water Management Plan
MFSG – Montebello Forebay Spreading Grounds, which include the Rio Hondo Spreading Grounds, San Gabriel River Spreading Grounds, and the unlined portion of the San Gabriel River in the Montebello Forebay
Existing – Implementation measures or projects/programs/strategies that are currently in place
Planned – Implementation measures that are anticipated to be in operation before 2025, notwithstanding exigencies that are outside the control of the project sponsors
Conceptual – Implementation measures that have been hypothetically identified, but may or may not begin by 2025
a – Costs were obtained from Greater Los Angeles County IRWMP, 2013; online Project Tracking and Integration [http://irwm.rmcwater.com/la]; CH2MHILL, 2012a; costs are estimated totals for completion of the project including planning, design, construction, and permits; personal communication from Phuong Ly of WRD, March 19, 2014 regarding estimated costs for SNMP monitoring program

Although impacts from some implementation measures could not be quantitatively assessed, it is clear that each implementation measure, based on the details of the project/strategy, will reduce S/N loading and/or improve groundwater quality, as indicated in Table J-6.

As shown in Table J-6, the implementation measures are grouped into the following categories: seawater intrusion control, groundwater recharge, institutional, stormwater capture/runoff management, source water salinity control, wastewater salinity/nutrient source control, total maximum daily loads (TMDLs), conservation, public education, regulatory/non-regulatory, and land use regulation. Generally, projects that improve stormwater, wastewater, and recycled water quality, increase stormwater recharge, increase AWT recycled water recharge, and reduce sources of S/N loading provide for improved groundwater quality are considered implementation measures.

Individual implementation measures listed in Table J-6 are described in detail below, organized by the existing, planned, and conceptual categories and implementation measure (IM) numbers correspond to the numbers shown in the third column from the left in Table J-6.

6.2.1 Existing Implementation Measures

The existing implementation measures are listed as IM 1 through IM 29 in Table J-6 and described in detail below. Since these implementation measures are projects/programs that have already been put into place, they are considered part of the baseline conditions.

SEAWATER INTRUSION CONTROL

<u>IM 1. Seawater Intrusion Barriers (WCBB, DGB, and AGB)</u> – The seawater intrusion barriers are existing implementation measures, which manage the saline intrusion as well as provide groundwater recharge in the CBWCB. Historically, both imported water and advanced treated recycled water were delivered to the seawater barriers for injection. As discussed further in Section 6.2.2 (Implementation Measure No. IM 30), AWT recycled water is expected to be replace imported water at all three seawater barriers during the future planning period.

The AGB began operating in the early 1960s along the southern border of the Central Basin. Historically, the AGB received only treated imported water for injection, but began also utilizing AWT recycled water in 2005. The AWT recycled water is produced by WRD's Leo J. Vander Lans Advanced Water Treatment Facility (Vander Lans AWTF) and the treated imported water is provided by the Metropolitan Water District of Southern California (MWD). Advanced treatment processes at the Vander Lans AWTF currently include microfiltration (MF), reverse osmosis (RO), ultraviolet irradiation (UV), and advanced oxidation (AOP) through the addition of peroxide.

The WCBB began operating in the mid-1950s along the western coast of the West Coast Basin. Historically, the WCBB received only treated imported water for injection, but began also utilizing AWT recycled water in 1995. The AWT recycled water is produced by West Basin Municipal Water District's (WBMWD's) Edward C. Little Water Recycling Facility (Edward C.

Little WRF) and the treated imported water is provided by MWD. Treatment processes at the Edward C. Little WRF include MF, RO, AOP, ozonation (O_3), and chemical stabilization.

The DGB began operating in the early 1970s in southern portion of the West Coast Basin. Currently, AWT recycled water produced by the City of Los Angeles' Terminal Island Water Reclamation Plant/Advanced Water Treatment Facilities (TIWRP) and treated imported water from MWD are delivered to the DGB for injection. The TIWRP treatment train currently includes MF, RO, and chlorination. Historically, the DGB received only treated imported water, but began also utilizing AWT recycled water in 2006.

As shown in Table J-4, AWT recycled water is significantly lower in TDS and chloride compared with imported water, but nitrate levels are very low and comparable in both water sources. As such, the partial replacement of imported water with AWT recycled water at the barriers continues to significantly reduce TDS and chloride loading and concentrations in groundwater in the CBWCB.

IM 2. Desalters – The C. Marvin Brewer Desalter (Brewer Desalter) and Robert W. Goldsworthy Desalter (Goldsworthy Desalter) are existing facilities that treat brackish groundwater pumped from wells located in areas impacted by seawater intrusion in the West Coast Basin, thereby increasing the outflow of S/Ns from the basin and reducing S/N concentrations in groundwater.

The desalters are operating in the City of Torrance. The Brewer Desalter has a design capacity of 1,200 AFY and is owned by WBMWD and operated by California Water Service Company, who distributes the treated water as part of its potable supply.

The Goldsworthy Desalter has a design capacity of 2,800 AFY and currently operates at about 2,200 AFY. It is owned by WRD and is operated and maintained by the City of Torrance, who delivers the treated water to their drinking water system.

GROUNDWATER RECHARGE

IM 3. Dominguez Gap Spreading Grounds (DGSG) Existing Operations – Stormwater is currently captured at the DGSG and recharges the West Coast Basin. Historically, the DGSG recharged both the Central Basin and West Coast Basin. Recharge of stormwater adds S/N load but decreases concentrations because stormwater has lower S/N concentrations compared with ambient groundwater.

IM 4. Montebello Forebay Spreading Grounds Existing (MFSG) Operations – Currently, the MFSG uses tertiary-treated recycled water, untreated imported water, and stormwater for groundwater recharge. Although current recharge operations at the MFSG increase S/N loading, future water quality projections as determined from the SNMP analysis indicate that the current blend of recharge water results in declining S/N concentrations in groundwater in the Montebello Forebay.

IM 5. MFSG Interconnection Pipeline – The interconnection pipeline between the Rio Hondo Spreading Grounds and San Gabriel River Spreading Grounds, completed in 2011, allows greater operational flexibility and increases stormwater capture by about 1,300 AFY (CH2MHILL, 2012b), thereby increasing S/N loading, but reducing S/N concentrations in groundwater.

IM 6. Rio Hondo Spreading Grounds (RHSG) Basin 6E to 8E Connection – Construction of a connection from RHSG Basin 6E to 8E is an existing project that allows for increased flexibility and the capture of an additional 1,200 AFY of replenishment water, thereby increasing S/N loading, but reducing S/N concentrations in groundwater.

IM 7. San Gabriel River Rubber Dams – Additional rubber dams recently installed in the San Gabriel River above the Whittier Narrows Dam increase the amount of stormwater capture by about 3,600 AFY (Johnson, 2011; CH2MHILL, 2012b), thus increasing S/N loading, but reducing S/N concentrations in groundwater.

IM 8. Whittier Narrows Dam Conservation Pool Project – Operational enhancements are being implemented to increase the conservation pool elevation behind the dam from 195 to 205 feet above mean sea level (ft-msl). The project is being implemented in phases. In 2004, the conservation pool elevation behind the dam was raised to 201.6 ft-msl, resulting in an estimated additional capture of about 3,000 AFY of stormwater (Weeks, 2013), thereby increasing S/N loading, but reducing S/N concentrations in groundwater.

INSTITUTIONAL

IM 9 and IM 10. CBWCB Adjudication, Central Basin Judgment Amendment, and Groundwater Management Agency (WRD) – As described in Section 2, the following are existing institutional implementation measures currently in place:

- CBWCB judgments that adjudicated the basins and established other provisions,
- Central Basin judgment amendment issued in December 2013,
- Establishment of a groundwater management agency (WRD), and
- Multiple WRD programs, including the Safe Drinking Water Program, Groundwater Contamination Prevention Program, Regional Groundwater Monitoring Program, Hydrogeology Program, In-Lieu Program, and Water Independence Now (WIN) Program.

Due to significant overdraft in the CBWCB by the mid-1900s, the courts adjudicated the two basins to put a limit on pumping. The West Coast Basin judgment adjudicated the basin in 1961 and limited groundwater extractions to 64,468 AFY. The Central Basin judgment adjudicated the basin in 1965 and limited groundwater extractions to 217,367 AFY. While reduced pumping reduces S/N outflow from the basins, the net effect is reduced loading and improved groundwater quality due to reduced seawater intrusion.

To more efficiently manage the CBWCB and allow flexibility for basin pumpers, the judgments established provisions for carryover of unused annual pumping rights in any given year and an exchange pool wherein water rights not used by one party can be made available to another. A provision in the Central Basin judgment further allows additional carryover of pumping rights during a period that is declared by the WRD as a Water Emergency. The intent of this "drought carryover" provision is to prevent degradation of the groundwater basins by helping to restore groundwater levels and improving the water supply in the aquifers and provide an incentive to groundwater producers in the Central Basin to reduce pumping for a particular period of time under drought conditions.

On December 18, 2013, an amendment to the judgment for the Central Basin was issued by the courts. The amendment enables large-scale changes in the management practices within the basin, which are expected to enhance opportunities to develop recycled water for recharge and improve the capability to utilize the basin's storage for conjunctive use. As a result of the judgment amendment, the Watermaster in the Central Basin is now comprised of three entities: 1) Administrative Body, 2) Water Rights Panel, and 3) Storage Panel. WRD was designated as the Administrative Body and is responsible for preparing the annual *Watermaster Service* reports and submitting them to the Water Rights Panel. The Water Rights Panel is ultimately responsible for submitting the final *Watermaster Service* reports to the Superior Court of the State of California for filing.

WRD was established in 1959 for the purpose of protecting and preserving groundwater in the CBWCB. Accordingly, WRD is enabled under the California Water Code to provide the needed supplemental replenishment water to make up the difference between the adjudicated amounts and the natural safe yield. The process of supplementing natural groundwater recharge with additional recharge is known as artificial replenishment or managed aquifer recharge. In addition to facilitating groundwater recharge, WRD monitors and reports on groundwater quality and cooperates with various regulatory agencies to protect groundwater quality. Increased recharge increases S/N loading, but improves groundwater quality.

In order to ensure that the use of recycled water for groundwater recharge remains a safe and reliable practice, WRD participates in various research and monitoring activities, proactively contributes to the regulatory and legislative development processes, and engages in information exchange and dialogue with regulatory agencies and other recycled water users. WRD continues to closely coordinate with the SDLAC, which produces the recycled water used for surface spreading in the Montebello Forebay, on permit compliance activities, including groundwater monitoring, assessment, and reporting. Many monitoring and production wells are sampled frequently by WRD staff, and the results are reported to the regulatory agencies.

In addition to compliance monitoring and sampling associated with the spreading grounds, WRD is partnering with others to more fully investigate the effectiveness of soil aquifer treatment during groundwater recharge. Research is underway to more fully characterize the percolation process and to quantify the filtering and purifying properties of the underlying soil with respect to constituents of concern, such as nitrogen, total organic carbon, and chemicals of emerging concern (CECs). WRD continues to be vigilant in monitoring research on the occurrence, significance, attenuation, and removal of CECs, including pharmaceuticals, endocrine disruptors, and personal care products.

Three separate groundwater tracer studies were performed in 2003-2005, 2005-2006, and 2010-2011 for the purpose of tracking and verifying the movement of recycled water from the spreading grounds by testing the monitoring wells and the production wells. Results showed that the depth rather than the horizontal distance from the recharge ponds is the key factor influencing arrival times of recycled water to wells. Travel time to deeper wells is greater than to shallower wells, even if the deeper wells are very near the spreading grounds. In some cases, WRD made modifications to wells to seal off their shallow perforations so that the wells would only produce from the deeper aquifers. Tracer tests subsequent to well modification demonstrated an increased travel time compared to earlier results. These efforts, in addition to periodic studies assessing health effects and toxicological issues, are necessary to provide continued assurances that the use of recycled water for groundwater recharge remains safe and compliant with all regulatory standards.

The Safe Drinking Water Program was implemented by WRD in 1991 to promote the cleanup of groundwater resources at specific well locations. As part of this program, WRD provides grants and loans to pumpers in the CBWCB to install wellhead treatment facilities at active production wells that have been impacted by naturally-occurring constituents and man-made chemicals. A total of 16 wellhead treatment systems have been constructed. This program not only helps to remediate groundwater contamination plumes, but also helps to maintain a sustainable water supply by reducing reliance on imported water for potable supply.

In an effort to minimize or eliminate threats to groundwater supplies, WRD established the Groundwater Contamination Prevention Program. As part of this program, WRD created and administers the CBWCB Groundwater Contamination Forum, a data-sharing and discussion forum with key stakeholders that include the United States Environmental Protection Agency (USEPA), California Department of Toxic Substances Control (DTSC), LARWQCB, CDPH (now the SWRCB Division of Drinking Water), United States Geological Survey (USGS), and various cities and drinking water purveyors. In 2005, these stakeholders drafted and signed a Memorandum of Understanding, agreeing to meet regularly and share data on groundwater contaminated sites within the CBWCB. As a key stakeholder, WRD has been tracking and working in close consultation with the regulatory agencies to provide data and technical support to expedite investigations and cleanups at priority groundwater contaminated sites within the CBWCB.

WRD has been monitoring groundwater quality (including S/Ns) and water levels in the CBWCB for over 50 years. The Regional Groundwater Monitoring Program provides for the collection of basic information used for groundwater basin management including groundwater level data and water quality data. It currently consists of a network of over 300 WRD and USGS-installed monitoring wells at over 50 locations throughout the CBWCB, supplemented by the existing groundwater production wells operated by the water purveyors. Annually, WRD collects nearly 600 groundwater samples from its nested monitoring well network and analyzes them for over 100 constituents to produce nearly 60,000 individual data points to help track groundwater quality. The information generated by this program is compiled and evaluated in WRD's annual Regional Groundwater Monitoring Report, which are available for downloading from the WRD website (http://www.wrd.org/engineering/groundwater-engineering-reports.php). The Regional Groundwater Monitoring Report provides water quality summary tables (including data for TDS, chloride, nitrate) for each of the nested monitoring wells, water quality maps for the nested wells and drinking water wells, and maps and hydrographs depicting groundwater level data.

WRD is also the designated groundwater monitoring entity for the CBWCB under the State of California's California Statewide Groundwater Elevation Monitoring (CASGEM) program. WRD collects water level data from 28 of its nested monitoring wells and uploads it to the State's CASGEM website on a regular basis for seasonal and long-term water level trend tracking. Public access to the CASGEM website is at: www.water.ca.gov/groundwater/casgem.

Work performed under WRD's Hydrogeology Program includes the preparation of an annual Engineering Survey and Report, which incorporates the calculation and determination of annual overdraft, accumulated overdraft, changes in storage, pumping amounts, and replenishment water availability to help assess groundwater replenishment needs and costs in the ensuing year. Maps are created to show water levels in the basins and groundwater production patterns and amounts. Much of this information is published in Technical Bulletins, which are two-page documents that summarize groundwater issues of importance in the CBWCB. WRD continuously works with the USGS to better characterize the hydrogeologic conditions in the basins by compiling and interpreting the extensive amounts of data generated during drilling and logging of the WRD/USGS monitoring wells and collected from historical information for production wells and oil wells within the CBWCB. The final conceptual model will significantly improve the understanding of the aquifer depths, extents and thicknesses throughout the basins, and will assist pumpers and other basin stakeholders with planning for groundwater resource projects such as new well drilling, storage opportunities, or modeling.

WRD's In-Lieu Program plays an important role in the conjunctive use of the CBWCB, utilizing surplus imported water to lower the annual overdraft and reduce artificial replenishment needs. The In-Lieu Program helps provide an alternate means of replenishing the groundwater supply by encouraging basin pumpers to purchase surplus imported water when available instead of pumping groundwater, which lowers the annual overdraft and reduces artificial replenishment needs. The goal of the In-Lieu Program is to replenish in those areas which are not easily recharged through surface spreading due to their distance from the MFSG and/or location in deep confined aquifers. When wells are turned off, groundwater levels rise and water remains in storage that would have otherwise been pumped out.

WRD established the WIN Program to develop local and sustainable sources of water for use in groundwater replenishment activities. This has become increasingly important in light of persistent drought conditions in the State and environmental and regulatory issues that limit delivery of imported water to the Los Angeles area. As part of the WIN Program, the Groundwater Reliability Improvement Program (GRIP) was established to offset the current use of imported water by providing up to 21,000 AFY of alternative supply sources (e.g., recycled water, stormwater) for replenishment at the MFSG. The primary goals of GRIP are to:

- Provide a sustainable and reliable supply for replenishing the basins;
- Protect groundwater quality;
- Minimize the environmental/energy footprint of any option or options selected;
- Comply with pertinent regulatory requirements employing an institutionally feasible approach;
- Minimize cost to agencies using ground water; and
- Engage stakeholders in the decision making process.

Two recycled project alternatives were proposed as part of GRIP, GRIP Recycled Water Project A (GRIP A) and GRIP Recycled Water Project B (GRIP B), as further discussed in Section 7.2.

SOURCE WATER SALINITY CONTROL

IM 11. LACDPW Stormwater "First Flush" Policy – As described in WRD's Replenishment Operations Manual (September 2007), typically at least the first several hours of flow (e.g., the "first flush") of the first season's stormwater event is bypassed around the MFSG and DGSG and wasted to the ocean because it is too high in turbidity and contains trash. This first flush is also believed to contain higher concentrations of pollutants, and thus conducting first flush potentially lowers S/N loading and improves groundwater quality.

IM 12. MWD Salinity Source Water Control Program – The MWD imports supplemental water supplies to the Southern California region, which includes the CBWCB. These supplies are imported from the Colorado River (CR) via the Colorado River Aqueduct and the Sacramento-San Joaquin Bay Delta (Delta) via the State Water Project (SWP). The salinity of these imported supplies is managed through source control measures, collaborative actions with other agencies, distribution system salinity management, and participation with local agencies to protect groundwater and recycled water supplies. Source control measures are critical for reducing salinity in imported water supplies and protecting groundwater supplies from additional salinity[5]. Salinity control programs and studies are described below.

- Colorado River Basin Salinity Control Program – The program provides Federal appropriations for salinity reduction projects. These projects include irrigation improvement practices, rangeland management, and deep well brine injection which aid in meeting the program's salinity numerical objectives for the Colorado River Basin.
- California Department of Water Resources Municipal Water Quality Investigations Program – The program, funded through the SWP Contractors, provides routine and real-time monitoring and forecasting of salinity levels in the Delta and SWP.
- Future SWP Activities – The proposed Bay Delta Conservation Plan could significantly reduce TDS levels of exported SWP supplies. If the plan is implemented, the Sacramento River would bypass the Sacramento -San Joaquin Delta and feed directly into the SWP, reducing TDS levels in the SWP supply.
- Update of the 1999 Salinity Management Study – The 1999 Study is being updated through a partnership between MWD, the United States Bureau of Reclamation, and the Southern California Salinity Coalition. The Update will seek to effectively quantify and set goals for managing the effects of salinity on water resources in Southern California.

Collaborative actions with other agencies allow MWD to exchange water supplies, thereby providing its service area with lower salinity water as described below.

- MWD exchanges CR supplies for lower salinity SWP supplies with the Desert Water Agency and the Coachella Valley Water District. These water agencies contract for SWP supplies, but are unable to take direct delivery of these supplies.

---

[5] Information provided by Kathy Kunysz, Metropolitan Water District, July 31, 2012

- As opportunities arise, MWD also exchanges some of its SWP supplies for higher quality runoff from the Sierra Nevada mountain range as part of its storage and recovery operations with San Joaquin Valley irrigation districts.

MWD delivers a blend of CR water and SWP supplies to the CBWCB and this imported water is treated by three of MWD's drinking water treatment plants: two blended water plants (Weymouth and Diemer WTPs) and one SWP plant (Jensen treatment WTP).

- 1999 Salinity Management Policy – MWD continues to support long-term salinity control by considering the 500 mg/L annual TDS goal in its operations by blending water from the SWP and CR. The anticipated Update of the 1999 Salinity Management Study will assess MWD's future operational capability to deliver low salinity water supplies through 2020.

MWD works with local agencies to manage salinity to protect the quality of groundwater resources and enhance the quality of recycled water.

- Multiple-Agency Collaboration – The Southern California Salinity Coalition, formed in 2002, focuses on coordinating salinity management strategies and programs, including research projects, with water and wastewater agencies throughout Southern California. Refer to Project No. 20 for a further description of the Southern California Salinity Coalition.
- In addition, the Multi-State Salinity Coalition was formed in 2001 to advance the development of local and regional projects and programs associated with desalination and salinity management technologies, practices, funding, and implementation.
- Local Salinity Management Projects – Various Southern California agencies are undertaking salinity management studies and projects related to brine concentrate disposal, water softener management, and desalination projects.
- Local Resources Program – MWD encourages the recovery and cleanup of saline groundwater through its Local Resources Program. This program provides financial payments of up to $250 per acre-foot of water supply yield created through desalters.

STORMWATER CAPTURE/RUNOFF MANAGEMENT

IM 13. City of Torrance Retention Basins – Based on the Greater Los Angeles County Integrated Regional Water Management Plan (GLAC IRWMP) Online Project Tracking and Integration (OPTI) website, there are several projects that are considered implementation measures for the CBWCB. Currently, the City of Torrance operates a number of stormwater retention basins, some of which (the Bishop Montgomery, Del Amo, and Ocean basins) allow for recharge and groundwater replenishment. This project increases stormwater capture, which increases S/N loading but reduces S/N concentrations in groundwater due to the relatively low S/N concentrations in surface water/stormwater compared with ambient groundwater.

IM 14. Low Impact Development (LID) and Stormwater Best Management Practices (BMPs) – LID includes design techniques that infiltrate, filter, store, evaporate, and detain surface water runoff close to its source. BMPs address the increased volume and rate of runoff from impervious surfaces and the concentration of pollutants in the runoff. BMPs can include structural systems such as infiltration devices, ponds, filters and constructed wetlands. BMPs can also include non-structural BMPs such as LID practices to preserve/recreate natural landscape features or minimize effective imperviousness and management measures such as maintenance practices, street sweeping, public education, and outreach programs. The main goals of LID and stormwater BMPs are to increase groundwater recharge and improve stormwater quality. There are multiple existing and planned LID and stormwater BMPs in the CBWCB. These projects/practices decrease S/N loading and concentrations in groundwater.

IM 15. LARWQCB Municipal Separate Storm Sewer System (MS4) Permit for Los Angeles County – In 2001, the LARWQCB issued the National Pollutant Discharge Elimination System (NPDES) permit (2001 MS4 Permit; Order No. 01-182, NPDES No. CAS004001) for MS4 discharges for 84 cities and a majority portion of the unincorporated areas of Los Angeles County. Some cities within the CBWCB, such as the City of Long Beach, have a separate MS4 NPDES permit. The 2001 MS4 Permit regulated the discharge of runoff from MS4s or storm drains, prohibited non-stormwater discharges into the storm drain system, and limited any discharges to receiving waters that would cause or contribute to a violation of water quality standards. The 2001 MS4 Permit required implementation of a Stormwater Quality Management Plan that included the use of BMPs to reduce the amount of pollutants in stormwater and dry-weather runoff.

In December 2012, the LARWQCB adopted a new MS4 Permit (Order No. R4-2012-0175; http://www.waterboards.ca.gov/rwqcb4/water_issues/programs/stormwater/municipal/index.shtml) that replaced the 2001 MS4 Permit. The 2012 MS4 Permit differs significantly from the 2001 MS4 Permit in several respects, including new requirements for hydromodification[6] and LID that apply to existing development or redevelopment projects that have been constructed or for which grading or land disturbance permits have been submitted and are deemed complete prior to the adoption date of the 2012 MS4 Permit. Significantly, permittees are encouraged to infiltrate stormwater as a fundamental aspect of permit implementation. Additional details regarding the MS4 permits in Los Angeles County can be found in the SNMP *Monitoring Plan* (Appendix K of the SNMP). Overall, MS4 permits in the CBWCB decrease S/N loading and concentrations in groundwater.

WASTEWATER SALINITY/NUTRIENT SOURCE CONTROL

IM 16. Industrial Wastewater Source Control Programs – Within the CBWCB, SDLAC and the City of Los Angeles Bureau of Sanitation (LABOS) operate pretreatment programs that regulate industrial and commercial discharges into the agencies' wastewater management systems.

---

[6] Hydromodification can be any activity that increases the velocity and volume (flow rate), and often the timing, of runoff. Such activities include: construction and maintenance of channels, levees, dams, and other water conveyance structures and/or impoundments for purposes of flood control, water storage, water conveyance, and navigation; dredging and/or filling or other alterations to natural land contours for the purposes of new development (including transportation and other infrastructure) or navigation; development of impervious surfaces (asphalt, concrete, most buildings, etc.); and deforestation or removal of vegetation.

These activities are conducted in accordance with ordinances adopted by SDLAC and LABOS, Federal pretreatment regulations pursuant to Code of Federal Regulations, Title 40, Part 403, and the Clean Water Act. The source control programs permit, inspect, monitor, develop source control and pollution prevention requirements, and take enforcement actions for permit and ordinance violations. The overall objectives of the programs are to:

- Protect water treatment plants (WTPs) and water reclamation plants (WRPs) from interference with process operations and pass through of harmful pollutants to the environment;
- Protect the life, health, and safety of operating and maintenance personnel;
- Ensure the health, safety, and welfare of the public;
- Provide the opportunity for beneficial reuse of biosolids; and
- Provide the opportunity for water reclamation.

Each agency's ordinance allows for the development of industrial and commercial discharge requirements to protect the quality of recycled water and meet Waste Discharge Requirements/Water Recycling Requirements (WDR/WRR) and NPDES limits, including S/Ns. This can be accomplished by establishing industry-specific or industrial category-specific discharge limits, requiring industries to bypass discharges around WRPs, prohibiting the use of self-regenerating water softeners (SRWS), requiring implementation of pollution prevention BMPs, and conducting public outreach. Thus, these programs help to reduce S/N loading and concentrations in groundwater.

IM 17. Wastewater and Recycled Water Nitrogen Treatment – Within the Los Angeles Region, wastewater treatment plants that discharge to inland surface waters have implemented nitrification-denitrification (NdN) as part of their secondary biological treatment processes to reduce nitrogen concentrations. The biological conversion of ammonia in sewage to nitrate-nitrogen is called nitrification. The biological reduction of nitrate to nitrogen gas by facultative heterotrophic bacteria is called denitrification. By 2003, SDLAC converted its WRPs to include NdN to meet NPDES discharge limits for ammonia, nitrate, and nitrite that are based on BPOs. The NdN modifications have achieved meaningful reductions in total nitrogen and therefore, help to reduce nutrient (nitrate) loading and concentrations in groundwater. As one example, the pre-NdN (1993 to mid-2003) average total nitrogen concentration in the San Jose Creek East WRP effluent was approximately 14 mg/L compared to the post-NdN (mid-2003 to 2011) average total nitrogen concentration of approximately 6.5 mg/L, a reduction of 53%. SDLAC documents NdN reductions for all of its WRPs.

IM 18. Residential Automatic Water Softeners Educational Outreach – Because self-regenerating water softeners (SRWS) rely on salt for water softening, which ultimately gets discharged to the sewer and wastewater treatment plants, they add significant salt loading to the tertiary-treated recycled water that recharges the CBWCB. The SDLAC and Santa Clarita Valley Sanitation District have done extensive outreach and education regarding SRWS in the Santa Clarita Valley in order to comply with the State's legal limit for chloride discharged to the Santa Clara River. The SDLAC's website provides information on SRWS, their groundwater quality impacts, and salt-free alternatives to SRWS (http://www.lacsd.org/wastewater/automatic_water_softeners/alternatives.asp). This program helps to reduce salt (TDS and chloride) loading and concentrations in groundwater. There currently are no plans within the CBWCB for mandated replacement of residential SRWS or to implement voluntary rebate programs.

PUBLIC EDUCATION

IM 19. Council for Watershed Health (CWH) – The CWH is an organization established in 1996 to facilitate a stakeholder-driven consensus process to enhance the economic, social, and ecological health of the region's watersheds through education, research, and planning. One of the goals of the CWH is to achieve regional sustainability through integrated natural resources management, including water resources management. CWH conducts active technical and outreach programs directed at professionals, the media, agencies, elected officials, and the public. This organization and its outreach efforts have the potential to decrease S/N loading and concentrations in groundwater.

IM 20. CBWCB SNMP – To promote the development of the CBWCB SNMP, an informational website was created (http://www.wrd.saltnutrient.com/). The website disseminates information regarding the SNMP, including a calendar of events and meetings, meeting agendas and minutes, meeting presentations, project schedules, contact information, deliverables, data, and weblinks to other reference materials. Once the CBWCB SNMP is finalized and the Basin Plan Amendment is adopted, S/N management measures, including the implementation measures, will be carried out. As a result, these efforts will reduce S/N concentrations in groundwater or maintain groundwater quality in accordance with Basin Plan objectives.

IM 21. Water Replenishment District of Southern California (WRD) – WRD has a website (http://www.wrd.org/index.php) that provides useful information on various recharge and water quality monitoring and protection programs. WRD also conducts numerous public meetings and events throughout the year to discuss the uses and benefits of recycled water, groundwater replenishment, and preserving groundwater quality. This agency and its outreach efforts have the potential to decrease S/N loading and concentrations in groundwater.

IM 22. Southern California Salinity Coalition (SCSC) – SCSC was formed in 2002 to address the critical need to remove salt from water supplies and to preserve water resources in California. SCSC is administrated by the National Water Research Institute (NWRI; http://nwri-usa.org/) and is a coalition of water and wastewater agencies in Southern California (including SDLAC and MWD) dedicated to managing salinity in the water supply. SCSC has partnered with MWD and United States Department of the Interior, Bureau of Reclamation (USBOR) to update the 1999 Salinity Management Study. As part of the effort, SCSC will be producing outreach and education materials on understanding Southern California salinity conditions and practices and identifying opportunities to promote effective regional salinity management. SCSC is working to update the regional salt balance by considering local and imported salinity sources and identifying trends (e.g., groundwater basin accumulation considering salt imports and exports); develop a tool to determine annual salinity indicators to assess the status of regional salinity management; identify regulatory approaches that affect salinity management and water resource development (e.g., SWRCB/RWQCB criteria for brine discharges, implementation of

SNMPs, water quality objectives for TDS, etc.); and assess the regional salinity impacts of compliance with SB X7-7 (refer to IM 24), including impacts to wastewater and receiving groundwater. This organization and its outreach efforts have the potential to decrease salt (TDS and chloride) loading and concentrations in groundwater.

SCSC maintains websites for outreach on salinity information (www.socalsalinity.org) and assessing impacts of salinity from irrigation (www.salinitymanagement.org). The SCSC website (www.socalsalinity.org) describes upcoming and past events hosted by SCSC and provides salinity-related publications such as fact sheets, research project reports, workshop summaries, and SCSC-funded projects.

IM 23. WateReuse Association and WateReuse Research Foundation – The WateReuse Association (http://www.watereuse.org/) is a nonprofit organization whose mission is to advance the beneficial and efficient uses of high-quality, locally produced, sustainable water sources for the betterment of society and the environment through advocacy, education and outreach, research, and membership. The WateReuse Research Foundation (http://www.watereuse.org/foundation) is an educational, nonprofit corporation that was established to conduct applied research on behalf of the water and wastewater community for the purpose of advancing the science of water reuse, recycling, reclamation, and desalination. The Foundation's research covers a broad spectrum of issues, including chemical contaminants, microbiological agents, treatment technologies, salinity management, public perception, economics, and marketing. The Foundation's research supports communities across the United States and abroad in their efforts to create new sources of high quality water while protecting public health and the environment. As an example, a recent WateReuse research project, supported by SDLAC, assessed no-salt alternatives to self-regenerating water softeners, which contribute a significant salt load to the wastewater system. The research identified commercially available, cost competitive, and effective alternatives. These organizations and their efforts help to reduce S/N loading and concentrations in groundwater.

CONSERVATION

IM 24. Senate Bill x7-7 and Other Activities – As recognized in the Department of Water Resources (DWR) Public Review Draft of the Water Plan Update 2013 (DWR, 2013), conservation is a fundamental component of the South Coast region’s water management planning. The South Coast Region includes all of Orange County and portions of Ventura, Los Angeles (including the CBWCB), San Bernardino, Riverside, and Sana Diego counties. Water agencies in the South Coast have been aggressively implementing water conservation since the 1990s. Many local water agencies are signatories to the California Urban Water Conservation Council (CUWCC) memorandum of agreement for urban water conservation and also have adopted Urban Water Management Plans (UWMPs) to ensure water supply reliability during normal, dry, and multiple dry years. These agencies implement best management practices (BMPs) and demand management measures contained in those documents. The backbone of MWD’s conservation program is the Conservation Credits Program (CCP), initiated in 1988, that contributes $195 per AF of water conserved to assist member agencies in pursuing urban BMPs and other demand management opportunities. All of the region’s water suppliers have water conservation programs for their customers which feature residential and commercial water saving tips, rebates for water efficient purchases (e.g., low - flow toilets, high - efficiency clothes washers, weather - based irrigation controllers), and tools for implementing landscape/garden improvements.

Local agencies are also developing water conservation master plans and conservation rate structures as well as working closely through integrated regional water management (IRWM) planning efforts to develop coordinated water efficiency programs. To these ends, the GLAC IRWMP (GLAC IRWMP Leadership Committee, 2014) has been developed to define a clear vision and direction for the sustainable management of water resources in the GLAC Region for the next 20 years, to present the basic information regarding possible solutions and the costs and benefits of those solutions, and to inspire the Region and potential funding partners outside this Region.

The Water Conservation Act of 2009 (Senate Bill [SB] x7-7) requires each urban retail agency to establish in its UWMP a reduction goal to help California achieve a 20% statewide reduction in daily per capita water use by 2020. SB x7-7 requires urban water suppliers to calculate baseline water use and set an interim 2015 (half the 2020 target) and 2020 water use targets. One hundred fifty - seven South Coast urban water suppliers have submitted 2010 urban water management plans to DWR. SB x7-7 provides options to meet these targets including shifting to more recycled water use. The UWMPs indicate the South Coast Hydrologic Region had a population-weighted baseline average water use of 188 gallons per capita per day with an average population-weighted 2020 target of 159 gallons per capita per day.

The GLAC IRWMP provides estimates of water conservation target volumes (water use efficiency excluding water recycling) for the CBWCB in 2035. These target volumes are believed to be a conservative estimate that would also be in effect in 2025 based on compliance with SB x7-7. The estimated water conservation target volumes in 2025 are shown in **Table J-7**.

Water conservation helps to ensure reliable water supplies by avoiding or efficiently using water, but can have mixed impacts on S/N loading. It has the potential to increase the TDS, chloride, and nitrate concentrations in wastewater discharged to the sewer due to reduced in-home water use. This is because the same amount of salt are added through use, but the total volume of water used is less. On the other hand, to the extent that conservation reduces irrigation and associated irrigation return flows, it will decrease S/N loading. Overall, SB x7-7 has the potential to reduce S/N loading and concentrations in groundwater, and is accordingly included as an implementation measure.

SDLAC evaluated its WRPs in the CBWCB in terms of flow reductions and changes in TDS and chloride[7] concentrations. While wastewater flows have declined starting in 1998, the TDS concentrations have remained steady and do not appear to be impacted by water conservation. However, chloride trends are a bit different. For the six facilities that make up SDLAC's Joint Outfall System (including the WRPs that provide recycled water in Central Basin), chloride has increased at the Joint Water Pollution Control Plant, La Cañada WRP, and Whittier Narrows

[7] Personal communication from Ann Heil, SDLAC, July 27, 2012.

Table J-7 2025 Estimated Water Conservation Target Volumes for Central Basin and West Coast Basin

2025 Estimated Water Conservation Target Volumes AFY	
Central Basin	West Coast Basin
2,300[a]	9,600[d]
5,700[b]	4,100[e]
6,500[c]	21,400[f]
Total = 14,500	**Total = 35,100**

AFY – acre-feet per year UWMP – Urban Water Management Plan

a. City of Los Angeles 2010 UWMP (broken down based on area within the Central Basin)
b. Long Beach Water Department 2010 UWMP
c. Central Basin Municipal Water District 2010 UWMP
d. West Basin Municipal Water District 2010 UWMP
e. Torrance 2010 UWMP
f. City of Los Angeles 2010 UWMP (broken down based on area of City of Los Angeles within the West Coast Basin)

WRP. SDLAC has observed a slight increase at the Pomona WRP and San Jose Creek East WRP, but since chloride concentrations appear to be cyclical at these plants, this trend is not definitive. Chloride levels are staying steady or dropping at the Long Beach, Los Coyotes, and San Jose Creek West WRPs, although this trend may be influenced by chloride industrial dischargers shutting down or being rerouted to other plants.

Assessment of the WBMWD's Edward C. Little WRF tertiary-treated recycled water quality (see Table I-9 in Appendix I) shows a significant increase in both TDS and chloride beginning in WY 2005-06, indicating that an increasing trend in salt due to conservation may be occurring. Based on these findings, the increased use of tertiary-treated recycled water for irrigation was simulated as part of the SNMP analysis for both the average of the baseline period (WY 2000-01 through 2009-10) and at higher concentrations through the future planning period (WY 2010-11 through 2024-25), as further discussed in Appendix I. Refer to Section 7 (Recycled Water Project Nos. RW 3 and RW 4) for a discussion of the results of the SNMP analysis.

REGULATORY/NON REGULATORY

IM 25. Wastewater, Recycled Water, Surface Water/Stormwater, Imported Water and Groundwater Monitoring – There are multiple recycled water, wastewater, imported water, surface water/stormwater, and groundwater monitoring programs within and upstream of the CBWCB. Details regarding these monitoring programs are provided in the SNMP *Monitoring Plan* (Appendix K of the SNMP). These monitoring programs provide a comprehensive and continuing assessment on all the types of water within and entering the CBWCB. Thus, the monitoring programs assist in the overall efforts to decrease S/N loading and concentrations in groundwater.

Under the various existing monitoring programs, groundwater has been and continues to be monitored near recycled water recharge sites, in production wells used for water supply, and in a large network of multiple completion monitoring wells for multiple decades. Groundwater from more than 1,500 wells[8] is sampled on a daily to annual basis. Hundreds of chemicals/analytical parameters are tested each year.

WRD's Regional Groundwater Monitoring Program is an existing voluntary monitoring program that currently includes of a network of over 300 nested groundwater monitoring wells installed at over 55 locations throughout the CBWCB. Annually, WRD collects nearly 600 groundwater samples from its monitoring well network and analyzes them for over 100 constituents to produce nearly 60,000 individual data points to help track groundwater quality. Each year, WRD publishes a Regional Groundwater Monitoring Report that provides water quality summary tables (including data for TDS, chloride, nitrate) for each of the nested monitoring wells, water quality maps for the nested wells and production wells, and maps and hydrographs depicting groundwater level data.

In addition to groundwater monitoring, the CBWCB and tributary areas have numerous, robust, and accessible monitoring programs for recycled water, wastewater, imported water, and surface water/stormwater for the three S/N indicators. In addition, hundreds of chemicals/analytical parameters, including constituents of emerging concern (CECs), are tested each year for multiple source waters. These existing monitoring programs are managed by multiple stakeholder agencies/organizations. Some programs, such as surface water/stormwater and wastewater monitoring, are part of the NPDES permits' Monitoring and Reporting Programs (MRPs), including regional watershed monitoring programs. Drinking water permits mandate imported water and groundwater monitoring. Non-potable reuse monitoring programs and groundwater recharge reuse monitoring programs for the Montebello Forebay Groundwater Recharge Project and the seawater intrusion barriers (WCBB, DGB, and AGB) are part of MRPs in each project's recycled water/reuse permit.

IM 26 and IM 27. State Regulations for Groundwater Replenishment using Recycled Water and LARWQCB Permits for Groundwater Recharge Projects – Regulations regarding groundwater replenishment (both surface and subsurface applications) using recycled municipal wastewater are specified in California Code of Regulations, Title 22, Division 4, Chapter 3, Articles 5.1 and 5.2. These regulations include a number of measures to ensure the protection of groundwater quality, including:

- An industrial pretreatment and pollutant source control program for the wastewater,
- Pathogenic microorganism control,

[8] The total number of wells that are sampled in the CBWCB on a regular basis far exceeds 1,500 because this estimated quantity only includes nested groundwater monitoring wells owned and sampled by WRD, existing production wells, and permit compliance monitoring wells associated with ongoing large recycled water projects in the basins, such as the Montebello Forebay Spreading Grounds and the three seawater intrusion barriers. This quantity does not include the numerous groundwater monitoring wells associated with existing environmental release sites in the CBWCB.

- Nitrogen compounds control,
- Regulated contaminants and physical characteristics control,
- Diluent water requirements,
- CEC monitoring,
- Demonstration that recycled water is retained underground for a period of time necessary to allow a response time sufficient to identify failure and implement actions necessary for the protection of human health,
- Calculation of the running monthly average recycled water contribution (RWC) based on the total volume of recycled water and credited diluent water that is recharged during the preceding 120 months,
- Chemical monitoring requirements for the recycled water and groundwater,
- Preparation of an Operation Optimization Plan that identifies and describes the operations, maintenance, analytical methods, and monitoring necessary to meet all groundwater recharge regulations,
- Groundwater monitoring well requirements, and
- Reporting to the SWRCB Division of Drinking Water (formerly CDPH) and LARWQCB.

Due to the potential for confusion and duplication of effort between CDPH and the RWQCBs, CDPH and the SWRCB signed a Memorandum of Agreement (MOA) in 1996. The MOA delineates responsibilities of each agency in review and approval of recycled water projects. As of July 1, 2014, under the direction of California Governor Jerry Brown, the administration of the Drinking Water Program was transferred from CDPH to the SWRCB to consolidate all major water quality programs within a single department, which will allow the State to better manage and protect water resources and ensure safe drinking water for all Californians. Thus, the State's drinking water and recycled water programs are now regulated under the SWRCB Division of Drinking Water. While the SWRCB Division of Drinking Water regulates public water systems and sets standards for wastewater reuse to protect public health (*Water Recycling Criteria* in Title 22 of the California Code of Regulations), the RWQCB has the permitting and ongoing oversight authority of groundwater recharge projects. SWRCB Division of Drinking Water requirements for permit approval are to be incorporated in the final permit that will be issued by the RWQCB.

IM 28. Recycled Water Non-Potable Reuse Regulations, Guidelines, and Permits – In January 1977 the SWRCB approved Resolution No. 77-1 which states, "*the California legislature has declared that the State shall undertake all possible steps to encourage the development of water reclamation facilities so that reclaimed water may be made available to help meet the growing water requirements of the State.*" The resolution also recognizes the need to protect public health from the environmental problems associated with reclamation projects. To this end, the SWRCB included in its July 1997 strategic plan a goal to meet this objective.

Recycled water has been used in California since the late 1800s. Public health restrictions have been in effect since the early part of this century. The regulations covering recycled water irrigation in California are found in California Health and Safety Code (CH&SC) Division 104, Part 12; California Water Code (CWC), Division 7; California Code of Regulations (CCR), Title 22, Division 4; and CCR, Title 17, Division 1, Chapter 5, Group 4. These documents can be found on the LARWQCB website (http://www.swrcb.ca.gov/losangeles/laws_regulations/).

Recycled water is an important resource for the State of California, and its use for non-potable applications is, in many cases, mandated by State law. Manuals have been developed to ensure protection of public health and compliance with regulations. Two manuals have been prepared for local recycled water users, as described below.

- The 2005 Los Angeles County Recycled Water User's Manual was compiled by the local chapter of WateReuse and includes the water and regulatory agencies involved with recycled water. The manual provides the recycled water "User" and "Site Supervisor" a resource for the day-to-day operation and control of that system. The manual outlines the process of converting to recycled water use in order to protect the health and welfare of the personnel involved with its use and the general public and to protect the quality of local water resources.
- The 2008 SDLAC Recycled Water Users Handbook provides information on the general rules, regulations, and guidelines regarding the safe use of tertiary-treated recycled water produced by SDLAC. The Handbook includes:
    - General information about SDLAC's water reuse program;
    - State and local standards, regulations, and guidelines for the use of recycled water;
    - Information on the duties and responsibilities of water purveyors and recycled water users;
    - Information on operational requirements at reuse sites; and
    - Information on notification and reporting.

Overall, recycled water non-potable reuse regulations, guidelines, and permits have the potential to reduce S/N loading and concentrations in groundwater in the CBWCB.

LAND USE REGULATION

IM 29. Model Water Efficient Landscape Ordinance – The Water Conservation in Landscaping Act of 2006 requires cities, counties, charter cities, and charter counties, to adopt landscape water conservation ordinances by January 1, 2010. Pursuant to this law, the Department of Water Resources (DWR) prepared a Model Water Efficient Landscape Ordinance (Model Ordinance) for use by local agencies. The Model Ordinance became effective on September 10, 2009.

All local agencies were required to adopt a water efficient landscape ordinance by January 1, 2010. The local agencies either adopted the State Model Ordinance, or crafted an ordinance to fit local conditions. In addition, local agencies could have collaborated to craft a region-wide ordinance. In any case, the adopted ordinance had to be as effective as the Model Ordinance in regard to water conservation.

The objectives of DWR's Model Water Efficient Landscape Ordinance are to:

- Promote the values and benefits of landscapes while recognizing the need to invest water and other resources as efficiently as possible;
- Establish a structure for planning, designing, installing, maintaining, and managing water efficient landscapes in new and rehabilitated projects;
- Establish provisions for water management practices and water waste prevention for established landscapes; and
- Use water efficiently without waste by setting a Maximum Applied Water Allowance as an upper limit for water use and reduce water use to the lowest practical amount.

Reduced irrigation, as stipulated by the Model Ordinance, reduces S/N loading and improves groundwater quality.

6.2.2 Planned Implementation Measures

The planned implementation measures are numbered IM 30 through IM 44 in Table J-6 and described in detail below. These projects/programs are expected to be implemented by the 2025 planning horizon of the CBWCB SNMP.

SEAWATER INTRUSION CONTROL

IM 30. Increase AWT Recycled Water Supply to Seawater Barriers (AGB, WCBB and DGB) – As described for Implementation Measure No. IM 1 in Section 6.2.1, the seawater intrusion barriers manage the saline intrusion as well as provide groundwater recharge in the CBWCB. Historically, both imported water and AWT recycled water were injected at each of the barriers. By or before the SNMP 2025 planning horizon, projects will be implemented at each of the barriers to allow for AWT recycled water to completely replace imported water for injection. This will require upgrades and expansion of source water treatment plants, along with potential construction of associated conveyance equipment such as pipelines and pump stations to convey the additional AWT recycled water to the three seawater barriers.

During WY 2014-15 when the Vander Lans AWTF was expanded to produce from 3,360 AFY to 8,960 AFY of AWT recycled water, the treatment train was modified to also include advanced oxidation (AOP) through the addition of peroxide. As planned, the expanded Vander Lans AWTF will produce 100% AWT recycled water (total of 7,200 AFY) for injection at the AGB, thus completely replacing the use of imported water. However, minor volumes of treated imported water, supplied by MWD, may be utilized as necessary through the future due to temporary operational and maintenance issues that may be encountered at the Vander Lans AWTF or at the AGB.

In WY 2013-14, the Edward C. Little WRF was expanded to produce from 14,000 AFY to 19,600 AFY of recycled water and the treatment train now includes ozonation (O_3). It was anticipated that AWT recycled water (total injection volume of 17,000 AFY) would fully replace imported water at the WCBB beginning in WY 2013-14. However, minor volumes of treated imported water, supplied by MWD, may be utilized as necessary through the future due to temporary operational and maintenance issues that may be encountered at the Edward C. Little WRF or at the WCBB.

The TIWRP is currently undergoing expansion activities to increase production of AWT recycled water. Once expansion of the TIWRP is complete in WY 2018-19, injection of 7,500 AFY into the DGB is planned to be 100% AWT recycled water, thus completely replacing imported water.

The SNMP mixing model was used to estimate the impacts of these seawater barrier projects on future groundwater quality. AWT recycled water is significantly lower in TDS and chloride compared with imported water, but nitrate levels are very low and comparable in both water sources. As such, the complete replacement of imported water with AWT recycled water at the seawater barriers will significantly reduce TDS and chloride loading and concentrations in groundwater. Groundwater quality in the CBWCB will continue to improve or remain well below WQOs.

IM 31. Increase Pump and Treat by the Desalters and Expansion of Goldsworthy Desalter – As described for Implementation Measure No. IM 2 in Section 6.2.1, the Goldsworthy Desalter is an existing facility that treats brackish groundwater extracted from an area inland of the WCBB that is impacted by historical seawater intrusion. The Goldsworthy Desalter has a design capacity of 2,800 AFY and currently operates at about 2,200 AFY. In 2015, the total plant capacity will be expanded to 5,500 AFY[9], which will allow increased groundwater pump and treat. In addition, average groundwater pumping for the Brewer Desalter is projected to increase in the future planning period compared with current pumping.

GROUNDWATER RECHARGE

IM 32. DGSG West Basin Percolation Enhancement – This planned project, described in the GLAC IRWMP, which will increase capture and percolation of stormwater at the DGSG in Long Beach in order to increase groundwater replenishment in the West Coast Basin.

The SNMP mixing model was used to estimate the impacts of this project in combination with other proposed projects in the CBWCB on future groundwater quality. Recharge of stormwater adds S/N load, but decreases concentrations in groundwater because stormwater has lower S/N concentrations compared with ambient groundwater. Modeling results show that groundwater quality in the CBWCB will continue to improve in the West Coast Basin and WQOs will be achieved in the future.

IM 33. MFSG New Turnout Structures – This planned project consists of the construction of two new turnout structures along the San Gabriel River in 2015 that will allow for more flexibility for the spreading of recycled water. The existing system restricts recycled water distribution to the San Gabriel River Spreading Grounds when stormwater is available for replenishment. Although recharge operations at the MFSG increase S/N loading, future water

---

[9] Personal communication from Ted Johnson, November 14, 2012.

quality projections as determined from the SNMP analysis indicate that groundwater quality in the Central Basin will remain well below WQOs.

IM 34. RHSG Sediment Removal – This planned project will restore percolation and storage capacity at the spreading grounds. The RHSG basins have approximately 450,000 cubic yards of sediment accumulated in them, which not only reduces the water storage capacity, but also the percolation capacity from 400 cubic feet per second to 200 cubic feet per second. The spreading basins are thus filled to capacity sooner, which results in reduced operational flexibility and having to bypass storm flows which reduces recharge of stormwater. This project would restore percolation and storage capacity, potentially yielding approximately 1,000 AFY of replenishment water by removing approximately 450,000 cubic yards of sediment accumulated in the spreading basins. The greater capacity will increase operational flexibility, thereby better accommodating the increasingly dynamic delivery schedules of imported water, recycled water, and stormwater. The estimated implementation date for the sediment removal is WY 2016-17.

Although recharge operations at the MFSG increase S/N loading, future water quality projections as determined from the SNMP analysis indicate that groundwater quality in the Central Basin will remain well below WQOs.

INSTITUTIONAL

IM 35. West Coast Basin Judgment Amendment – The adjudication decree for the West Coast Basin is in the process of being amended and anticipated to be completed by the SNMP 2025 planning horizon. The proposed amendments would enable large-scale changes in the management practices within the West Coast Basin. They will further enhance opportunities to develop recycled water for recharge and improve the capability to utilize the basin's storage for conjunctive use. There is a potential for this implementation measure to decrease S/N loading and concentrations in groundwater, depending on the final management strategies that are enacted as part of the judgment amendment.

STORMWATER CAPTURE/RUNOFF MANAGEMENT

IM 36 and IM 37. Additional LID Projects, Stormwater BMPs, and LARWQCB MS4 Permits – As described for Implementation Measure Nos. IM 14 and IM 15 in Section 6.2.1, there are multiple existing and planned LID projects and stormwater BMPs. Recent MS4 permits issued by the LARWQCB include new requirements for stormwater infiltration and reuse, hydromodification, and LID that apply to existing development or redevelopment projects that have been constructed or for which grading or land disturbance permits have been submitted and are deemed complete prior to the adoption date of the MS4 permit. It is anticipated that the MS4 permits and permit-related LID/BMP projects overall would decrease S/N loading and concentrations in groundwater in the CBWCB.

In the 2012 MS4 permit that was issued by LARWQCB for the 84 cities and a majority portion of the unincorporated areas of Los Angeles County, Enhanced Watershed Management Programs (EWMP) and Watershed Management Programs were required for development to increase stormwater and non-stormwater surface water capture, as well as improve surface water quality. Recharge of higher quality surface water will result in improved groundwater quality once these programs are implemented.

<u>IM 38. Los Angeles Basin Stormwater Conservation Study</u> – In recognition that imported water supplies to Los Angeles County are uncertain due to periodic droughts in Northern California and the Colorado River Basin, court decisions related to endangered species in the Bay Delta, potential allocations of Colorado River water, changing demographics, climate variability, and the competing interests for available water, the USBOR, Los Angeles County Flood Control District (LACFCD), and several local agencies have begun a study (2013) of the long-term flood control and water conservation impacts from projected population and climate conditions in the Los Angeles Basin. According to the California Department of Finance, the State's population as a whole is projected to increase by more than 35% while Los Angeles County's is projected to increase by approximately 18% by 2050. Projected larger population growth rates outside of Los Angeles County portends enormous pressure and competition for imported sources of water and the need for increased development of local water supply sources. The study to be completed in 2015 will recommend potential changes to the operation of stormwater capture systems, modifications to existing facilities, and development of new facilities that could help resolve future flood control and water supply issues. It is assumed that some of the study recommendations will increase stormwater capture and will be implemented before 2025.

<u>IM 39. Broadway Neighborhood Stormwater Greenway Project</u> – This planned project in the City of Los Angeles will improve surface water and groundwater quality by reducing pollutant discharges through a number of BMPs including subsurface infiltration basins, rain gardens, dry wells, and green streets. The project incorporates LID practices on residential parcels and streets that will infiltrate and retain dry and wet weather runoff. These practices will result in a variety of benefits, including: 1) reducing the rate and volume of stormwater runoff; 2) providing filtration for water quality improvement; and 3) providing on-site storage and infiltration of stormwater into the underlying aquifers of the CBWCB. The LID measures will also reduce pollutant loading into the Los Angeles River by infiltrating and retaining contaminated stormwater runoff at its source: from roof tops, alleys, and neighboring streets of a 32-acre tributary area. This project is expected to begin operation in 2015. Recharge of stormwater adds S/N load, but decreases concentrations in groundwater because stormwater has lower S/N concentrations compared with ambient groundwater.

<u>IM 40. Improvements to Entradero Storm Drain Channel for Stormwater Infiltration</u> – This planned project in the City of Torrance will modify the Entradero Storm Drain Channel to improve stormwater infiltration for bacteria TMDL compliance. The channel currently has an asphalt bottom and dirt slopes. The project would replace the asphalt bottom and natural sides of the channel with a continuous pervious material to improve infiltration of stormwater while maintaining vegetation on the slopes to improve slope stability. This project is expected to begin operation in 2015. Recharge of stormwater adds S/N load, but decreases concentrations in groundwater because stormwater has lower S/N concentrations compared with ambient groundwater.

IM 41. Vermont Avenue Stormwater Capture – The Vermont Median Stormwater Park project is a planned project in the City of Gardena that consists of construction of a median park on Vermont Avenue over a planned recycled water line. The new park/dedicated open space accommodates multiuse pathways (pedestrian and bike lanes), open space areas, native habitats, biofiltration systems, and other stormwater features. This project is expected to begin operation in 2017. Recharge of stormwater adds S/N load, but decreases concentrations in groundwater because stormwater has lower S/N concentrations compared with ambient groundwater.

TOTAL MAXIMUM DAILY LOADS (TMDLS)

IM 42. TMDLs – Section 303(d) of the Clean Water Act requires States and Territories of the United States to identify water bodies that do not meet water quality standards (e.g., the 303(d) list of impaired water bodies) and then to establish TMDLs for each water body for each pollutant of concern. The TMDL is a calculation of the maximum amount of a pollutant from point sources and nonpoint sources that a water body can receive and still meet water quality standards, within a margin of safety and considering seasonal variation. When a TMDL is approved, controls on pollutants are expected to be implemented for point sources through limits in NPDES permits and for nonpoint sources through other means, such as BMPs. TMDLs may help to reduce S/N loading and concentrations in groundwater.

CONSERVATION

IM 43. Senate Bill x7-7 and Other Activities – As described for Implementation Measure No. IM 24, conservation is a fundamental component of the GLAC water management planning, which has included aggressively implementing water conservation since the 1990s. Many local water agencies are signatories to the CUWCC memorandum of agreement for urban water conservation and also have UWMPs to ensure water supply reliability during normal, dry, and multiple dry years. The backbone of MWD's conservation program is the CCP, initiated in 1988, that contributes $195 per AF of water conserved to assist member agencies in pursuing urban BMPs and other demand management opportunities. All of the region's water suppliers have water conservation programs for their customers.

Local agencies are also developing water conservation master plans and conservation rate structures as well as working closely through IRWM planning efforts to develop coordinated water efficiency programs. To these ends, the GLAC IRWMP (GLAC IRWMP Leadership Committee, 2014) has been developed for the greater Los Angeles County area.

SB x7-7, enacted in 2009, requires each urban retail agency to establish in its UWMP a reduction goal to help California achieve a 20% statewide reduction in daily per capita water use by 2020. SB x7-7 requires urban water suppliers to calculate baseline water use and set an interim 2015 (half the 2020 target) and 2020 water use targets. One hundred fifty - seven South Coast urban water suppliers have submitted 2010 urban water management plans to DWR. SB x7-7 provides options to meet these targets including shifting to more recycled water use.

The GLAC IRWMP provides estimates of water conservation target volumes (water use efficiency excluding water recycling) for the CBWCB in 2035. Accordingly, existing water conservation efforts are planned to continue through the SNMP future planning period and beyond. Overall, SB x7-7 has the potential to reduce S/N loading and concentrations in groundwater, and is accordingly included as an implementation measure.

REGULATORY/NON REGULATORY

IM 44. SNMP Monitoring Program – The Recycled Water Policy requires development of a SNMP Monitoring Plan for each groundwater basin in California. The SNMP *Monitoring Plan*, provided as Appendix K in the SNMP, includes a detailed description of the SNMP Monitoring Program. The intent of the SNMP *Monitoring Plan* is to evaluate concentrations of S/Ns in groundwater with respect to applicable WQOs.

The SNMP Monitoring Program was developed based on WRD's Regional Groundwater Monitoring Program. Seventy (70) WRD nested groundwater monitoring wells (referred to as the SNMP monitoring wells) at 13 locations throughout the CBWCB were designated for S/N sampling and reporting to SWRCB's online GeoTracker database. Each nested well is screened in a specific aquifer, which allows the assessment of S/Ns in all the major aquifers of the CBWCB. In accordance to the Recycled Water Policy, these wells were selected based on their location in the most critical areas of the basins, particularly their proximity to water supply wells and groundwater recharge projects that utilize recycled water, including the seawater intrusion barriers and the MFSG.

WRD's annual Regional Groundwater Monitoring Report provides maps depicting chloride, TDS, and nitrate concentrations in the all the WRD nested groundwater monitoring wells and active purveyors' production wells, chloride and TDS trend graphs for the SNMP monitoring wells, and a discussion of S/N concentrations/trends in groundwater with respect to WQOs to assess overall groundwater quality in the CBWCB. These analyses provide the performance measures and evaluation of the effectiveness of the CBWCB SNMP implementation measures. Both WRD's Regional Groundwater Monitoring Program and the SNMP Monitoring Program provide the means for comprehensive assessment and reporting of S/N levels in groundwater in the CBWCB.

Once the LARWQCB has approved the SNMP and established a GeoTracker weblink for the SNMP Monitoring Program for the CBWCB, WRD will implement the SNMP Monitoring Program by collecting TDS, chloride, and nitrate data from the 70 SNMP monitoring wells on a semi-annual basis and uploading this water quality data to the GeoTracker database. It is anticipated that the SNMP *Monitoring Plan* will be implemented in 2015. The SNMP *Monitoring Plan* will be reviewed and updated as necessary as part of the SNMP update every ten years.

The SNMP Monitoring Program will assist in the overall efforts to decrease S/N loading and concentrations in groundwater in the CBWCB.

6.2.3 Conceptual Implementation Measures

The conceptual implementation measures are numbered IM 45 through IM 55 in Table J-6. These projects/programs/strategies are those that have been hypothetically identified, but may or may not begin after the SNMP 2025 planning horizon.

SEAWATER INTRUSION CONTROL

IM 45. Additional Desalters – Additional desalters and associated extraction wells were described as one of many potential CBWCB management alternatives in the Draft Groundwater Basins Master Plan (GBMP) (CH2MHILL, 2012b). This alternative would include seven additional desalter wells with a total capacity of 15,000 AFY. Since management alternatives developed and assessed in the GBMP are conceptual in nature and may or may not ultimately be implemented, the additional desalters and associated extraction wells are included as a conceptual implementation measure. Any additional desalters will increase the outflow of S/Ns from the basins, thereby reducing S/N concentrations in groundwater.

GROUNDWATER RECHARGE

IM 46. Additional Tertiary-Treated/AWT Recycled Water Recharge in the Montebello Forebay – As discussed in Section 7.2, GRIP recycled water projects are planned in the Montebello Forebay to recharge additional tertiary-treated recycled water and/or AWT recycled water at the MFSG. Other recycled water projects in the Montebello Forebay were described and assessed in the Draft GBMP (CH2MHILL, 2012b) to fully utilize SDLAC's San Jose Creek WRP and Los Coyotes WRP to provide up to an additional 45,800 AFY of tertiary-treated/AWT recycled water for spreading and injection. These potential future expansions were projected to occur beyond the SNMP 2025 planning horizon. Since management alternatives developed and assessed in the GBMP are conceptual in nature and may or may not ultimately be implemented, this alternative is included as a conceptual implementation measure. Depending on the type and amount of recycled water (tertiary-treated versus AWT) recharged, S/N loading could increase in the Central Basin, but S/N concentrations in groundwater could decrease since AWT recycled water has lower S/N concentrations than ambient groundwater quality. Potential impacts of any proposed groundwater recharge projects will be assessed in detail in the future and will be required to comply with all applicable State and Local regulations.

IM 47. Los Angeles River Aquifer Stormwater Recharge and Recovery Facility – In the Draft GBMP (CH2MHILL, 2012b), the Los Angeles River Aquifer Recharge and Recovery Facility (ARRF) Project is proposed as a CBWCB management alternative that would capture approximately 5,000 AFY of stormwater for recharge. Stormwater flows would be diverted to an infiltration basin along the Interstate 710 Freeway where it would percolate into the upper, shallow aquifer above the confining aquitard. The treated water would then be recovered (pumped) for subsequent injection through a vadose zone infiltration conduit into the Central Basin as a source of supplemental replenishment supply. This alternative would provide natural filtration to remove nitrate, pathogenic microorganisms, and constituents of emerging concern. Since management alternatives developed and assessed in the GBMP are conceptual in nature and may or may not ultimately be implemented, this alternative is included as a conceptual implementation measure. Recharge of stormwater adds S/N load, but decreases concentrations in groundwater because stormwater has lower S/N concentrations compared with ambient groundwater.

IM 48. Montebello Forebay Extraction and Intrabasin Transfer Project – This conceptual project is a CBWCB management alternative assessed in the Draft GBMP (CH2MHILL, 2012b).

For this project, 25,000 AFY of groundwater would be extracted in the Montebello Forebay to reduce groundwater levels, which would provide additional storage capacity and allow for 17,000 AFY of additional stormwater recharge. A pipeline would be constructed to deliver the extracted water from the Montebello Forebay to participating water purveyors as far south as the City of Long Beach. Since management alternatives developed and assessed in the GBMP are conceptual in nature and may or may not ultimately be implemented, this alternative is included as a conceptual implementation measure. This project is not anticipated to have an impact on S/N loading, but the extraction of groundwater could decrease S/N concentrations in groundwater.

IM 49. New Los Angeles Forebay AWT Recycled Water Recharge and Recovery – The Draft GBMP (CH2MHILL, 2012b) assessed the potential for a new replenishment supply in the Los Angeles Forebay produced by a new AWT recycled water facility. The facility, identified in the City of Los Angeles Recycled Water Master Planning, Groundwater Replenishment Master Planning Report (RMC, 2012a), would skim and treat wastewater from the major sewer trunk line otherwise destined for the Hyperion WTP. The facility could produce 45,480 AFY of AWT recycled water for groundwater recharge. This is a conceptual project that may or may not be implemented. Recharge of AWT recycled water in the Los Angeles Forebay will increase S/N loading, but will decrease S/N concentrations in groundwater since AWT recycled water would have lower S/N concentrations than ambient groundwater quality.

IM 50. Whittier Narrows Conservation Pool Project – As described for Implementation Measure No. IM 8 in Section 6.2.1, this next phase of the Whittier Narrows Conservation Pool Project will increase the conservation pool elevation behind the Whittier Narrows Dam from 201.6 to 205 ft-msl resulting in an estimated additional capture of 1,100 AFY of stormwater. This project is not expected to be implemented within the SNMP 2025 planning horizon. Recharge of stormwater adds S/N load, but decreases concentrations in groundwater because stormwater has lower S/N concentrations compared with ambient groundwater.

STORMWATER/RUNOFF MANAGEMENT

IM 51. Additional LID Projects and Stormwater BMPs – Additional LID projects and stormwater BMPs may be implemented in the CBWCB through the SNMP future planning period (refer to Implementation Measure Nos. IM 36 and IM 37 in Section 6.2.2). These projects are only conceptual at this time. Overall, LID/BMP projects potentially could decrease S/N loading and concentrations in groundwater.

WASTEWATER SALINITY/NUTRIENT SOURCE CONTROL

IM 52. Residential Self-Regenerating Water Softeners (SRWS) Control – There are currently no plans within the CBWCB for SDLAC or the City of Los Angeles to control residential SRWS or implement voluntary rebate programs. Thus, this project is only conceptual. While SRWS can add significant salt loading to the wastewater system, regulation of residential SRWS has historically been a very contentious issue and there are significant hurdles facing local agencies that wish to enact controls. Any efforts to control or reduce the use of SRWS would help to reduce salt (TDS and chloride) loading and concentrations in groundwater.

The State Health and Safety Code (California Code of Regulations, Section 116786) authorizes a local agency to prospectively limit the availability, or prohibit the installation, of residential water softening or conditioning appliances that discharge to the sewer system through adoption of an ordinance if the following findings are made, substantiated by an independent study, and included in the ordinance:

- Limiting the availability, or prohibiting the installation, of the appliance is a necessary means of achieving compliance with waste discharge requirements.
- The local agency has adopted and is enforcing regulatory requirements that limit the volumes and concentrations of saline discharges from nonresidential sources in the community waste disposal system to the extent technologically and economically feasible.

In 2009, Assembly Bill 1366 added Section 13148 to the California Water Code that provides other mechanisms to control residential SRWS. It only applies to specific hydrologic regions identified in the California Water Plan: the Central Coast, South Coast, San Joaquin River, Tulare Lake regions, and the Counties of Butte, Glenn, Placer, Sacramento, Solano, Sutter, and Yolo.[10] An agency is allowed to adopt an ordinance controlling residential SRWS if the applicable RWQCB makes a finding at a public hearing that the control of residential salinity input will contribute to the achievement of water quality objectives based on:

- A TMDL that addresses salinity-related pollutants in a water segment;
- A SNMP for a groundwater basin or subbasin;
- WDR, WRR, or master reclamation permit for a supplier or distributor of recycled water; or
- A cease and desist order directed to a local agency.

An adopted ordinance can among, many options, require the removal of previously-installed residential SRWS and/or prospectively prohibit the installation of residential SRWS. If the agency includes in its ordinance removal or replacement of previously installed softeners, it must develop a program to compensate the owner for the "reasonable value" of the removed residential SRWS.

If a regional wastewater management agency (such as SDLAC) were to adopt an ordinance, it has no legal authority to enter residences and enforce the ban. Consequently, each city or local government within the agency's regional service area would have to adopt its own ordinance to implement and enforce the prospective ban.

The SNMP analysis indicates that existing and planned implementation measures are adequate to manage S/N sources for the sustainable protection of groundwater quality. However, future updates to the SNMP may consider SRWS control measures if water quality changes in the future.

---

[10] See http://www.water.ca.gov/groundwater/bulletin118/gwbasin_maps_descriptions.cfm and http://www.water.ca.gov/groundwater/bulletin118/maps/statewide_basin_map_V3_subbas.pdf

IM 53. San Jose Creek East WRP Process Optimization – This conceptual project would provide flow equalization and treatment process upgrades, which would enable SDLAC's San Jose Creek East WRP to accept more wastewater and thereby produce more recycled water, either tertiary-treated or AWT. Further, flow equalization would make more recycled water available to water purveyors overnight when their demand is highest, thus facilitating increased recycled water use. This project is not expected to be implemented within the SNMP 2025 planning horizon and is therefore placed in the conceptual category. Depending on the type and amount of recycled water (tertiary-treated versus AWT) recharged or used for irrigation, S/N loading could increase in the Central Basin, but S/N concentrations in groundwater could decrease since AWT recycled water has lower S/N concentrations than ambient groundwater quality.

CONSERVATION

IM 54. Xeriscape Policy – Some water agencies in the CBWCB provide rebates for weather-based irrigation controls and turf removal programs for residential and commercial customers. Additional information is available on the MWD SoCal Water$mart website: http://socalwatersmart.com. These projects have the potential to reduce S/N loading and concentrations in groundwater in the CBWCB.

IM 55. Senate Bill x7-7 and Other Activities – As described for Implementation Measure Nos. IM 24 and 43, conservation is a fundamental component of the GLAC water management planning, which has included aggressively implementing water conservation since the 1990s. Many local water agencies are signatories to the CUWCC memorandum of agreement for urban water conservation and also have UWMPs to ensure water supply reliability during normal, dry, and multiple dry years. The backbone of MWD's conservation program is the CCP, initiated in 1988, that contributes $195 per AF of water conserved to assist member agencies in pursuing urban BMPs and other demand management opportunities. All of the region's water suppliers have water conservation programs for their customers.

Local agencies are also developing water conservation master plans and conservation rate structures as well as working closely through IRWM planning efforts to develop coordinated water efficiency programs. To these ends, the GLAC IRWMP (GLAC IRWMP Leadership Committee, 2014) has been developed for the greater Los Angeles County area.

SB x7-7, enacted in 2009, requires each urban retail agency to establish in its UWMP a reduction goal to help California achieve a 20% statewide reduction in daily per capita water use by 2020. SB x7-7 requires urban water suppliers to calculate baseline water use and set an interim 2015 (half the 2020 target) and 2020 water use targets. One hundred fifty - seven South Coast urban water suppliers have submitted 2010 urban water management plans to DWR. SB x7-7 provides options to meet these targets including shifting to more recycled water use.

The GLAC IRWMP provides estimates of water conservation target volumes (water use efficiency excluding water recycling) for the CBWCB in 2035. Accordingly, existing water conservation efforts are planned to continue through the SNMP future planning period and beyond. Overall, SB x7-7 has the potential to reduce S/N loading and concentrations in groundwater, and is accordingly included as an implementation measure.

7 Proposed Major Recycled Water Projects

Recognizing the potential negative impacts of climate change and drought, the use of recycled water by stakeholders in the CBWCB has played a vital role in increasing the reliability and sustainability of the overall water supply. Because one of the goals of the Recycled Water Policy is increased use of recycled water to reduce dependency on expensive, energy-intensive (due to pumping, distribution, and other costs), and increasingly unreliable imported water supplies, the CBWCB stakeholders are proposing some major recycled water projects for implementation while still protecting groundwater quality and beneficial uses.

Table J-8 describes the proposed major recycled water projects in the CBWCB, their estimated implementation dates, and their potential impacts to groundwater quality and S/N loading. The projects listed in Table J-8 are described in detail below and recycled water project (RW) numbers correspond to the numbers shown in the second column from the left in Table J-8. These projects are expected to be implemented by or before the SNMP 2025 planning horizon. Table J-8 is not inclusive of all recycled projects that may be implemented in the future in the CBWCB. As other recycled water projects are proposed throughout the SNMP future planning period, it is expected that each project will be implemented in accordance with all applicable regulations, including the California Environmental Quality Act (CEQA). The SNMP will be reviewed every 10 years, and Table J-8 will be updated accordingly.

Some of the proposed recycled water projects listed in Table J-8 (specifically Recycled Water Project No. RW 1), are also identified as implementation measures, since they are expected to reduce S/N loading and improve groundwater quality. Other recycled water projects listed in Table J-8 may add S/N load and increase S/N concentrations in groundwater. All the recycled water projects listed in Table J-8 were quantitatively assessed for their S/N groundwater quality impacts and use of assimilative capacity using the SNMP mixing model, as discussed further in Section 4.2.

The SNMP analysis demonstrated that projects that degrade groundwater quality are more than offset by projects (implementation measures) that improve groundwater quality. Further, an implementation plan that includes any of the combinations of projects described in Section 4.2, even including those that slightly degrade groundwater quality, is protective of groundwater quality and beneficial uses. None of the identified major recycled water projects use more than 10% of the available assimilative capacity of the Central Basin and in the West Coast Basin, where there is no available assimilative capacity, the combined projects improve groundwater quality with respect to TDS and chloride and have essentially no impact on nitrate in groundwater. Overall, the SNMP analysis demonstrated that implementation of the proposed major recycled water projects will result in groundwater quality remaining below BPO/BSBPOs in the Central Basin and BSBPOs for chloride and TDS being achieved in the future in the West Coast Basin. Nitrate in groundwater in both basins remains significantly below the BPO through the future.

Because the negative groundwater quality impacts of the proposed major recycled water projects have been demonstrated in the SNMP to be minimal and more than offset by implementation measures that improve groundwater quality, the SNMP may be used to

Table J-8 Proposed Major Recycled Water Projects in the CBWCB

Category	Recycled Water Project (RW) No.	Project Description	Basin	Cost [a]	Estimated Implementation Date	Impact to S/N Loading to Groundwater	Impact to S/N Concentrations in Groundwater
Seawater intrusion control	1	Increase AWT recycled water supply to all seawater intrusion barriers (WCBB, AGB, and DGB)	CBWCB	$206M	2017	Decrease	Decrease
Groundwater recharge	2A	GRIP A (AWT & tertiary-treated recycled water to replace imported water at MFSG)	CB	$490M	2017/18	No Change	No Change
	2B	GRIP B (tertiary-treated recycled water to replace imported water at MFSG)	CB	$183M	2014/15	Increase	Increase
Non-potable recycled water reuse	3	Increased non-potable reuse of recycled water for irrigation	CBWCB	N/A	Ongoing	Increase	Increase
	4	Recycled water quality limits at SMCLs for TDS and chloride and MCL for nitrate	CBWCB	N/A	Upon approval of the SNMP by LARWQCB	Increase	Increase

CBWCB – Central Basin and West Coast Basin
MFSG – Montebello Forebay Spreading Grounds
WCBB – West Coast Basin Seawater Intrusion Barrier
LARWQCB – Los Angeles Regional Water Quality Control Board
GRIP – Groundwater Reliability Improvement Program
CB – Central Basin
AGB – Alamitos Gap Seawater Intrusion Barrier
DGB – Dominguez Gap Seawater Intrusion Barrier
SNMP – Salt and Nutrient Management Plan
RW – Recycled Water Project
WCB – West Coast Basin
S/N – salt and nutrient
TDS – total dissolved solids
AWT – advanced water treatment
N/A – Not available

GRIP A – GRIP Recycled Water Project A, which utilizes a blend of tertiary-treated recycled water (11,000 acre-feet per year) and advanced treated (10,000 acre feet per year) recycled water to completely replace imported water for recharge at the Montebello Forebay Spreading Grounds

GRIP B – GRIP Recycled Water Project B, which utilizes 100% tertiary-treated recycled water to completely replace imported water for recharge at the Montebello Forebay Spreading Grounds

a – Costs were obtained from Greater Los Angeles County Integrated Regional Water Management Plan, 2013; online Project Tracking and Integration [http://irwm.rmcwater.com/la]; CH2MHILL, 2012a; costs are estimated totals for completion of the project including planning, design, construction, and permits.

provide a basis for streamlining of the permitting process for recycled water projects in the future in the CBWCB, per the Recycled Water Policy.

A program-level environmental analysis of the proposed major recycled water projects, as well as the implementation measures presented in Section 6, was conducted in accordance to California Environmental Quality Act (CEQA) requirements and results are presented in the Substitute Environmental Document (SED), which was prepared in conjunction with the SNMP and has been submitted to LARWQCB under a separate cover for review. The proposed projects will undergo their own individual CEQA analysis and will comply with all applicable rules and regulations before they can be implemented.

7.1 Seawater Intrusion Control Projects

RW 1. Increase AWT Recycled Water Supply to All Seawater Intrusion Barriers (AGB, WCBB and DGB) – Refer to description for Implementation Measure No. IM 30 in Section 6.2.2.

7.2 Groundwater Recharge Projects

As discussed in Section 6.2.1 (Implementation Measure No. IM 10 in Section 6.2.1), two GRIP recycled water project alternatives, GRIP A and GRIP B, were proposed by WRD to completely replace imported water (up to 21,000 AFY) with a reliable alternative supply source (i.e. recycled water) for recharge at the MFSG. Both GRIP A and GRIP B, are currently being considered for implementation and are described below as Recycled Water Project Nos. RW 2A and RW 2B, respectively.

The GRIP A and GRIP B alternatives are the end result of many studies conducted over a number of years to assess multiple potential projects to improve water supply reliability in the face of imported water supply uncertainties and increasing costs. These studies evaluated a wide spectrum of projects, including consideration of different levels of recycled water treatment and blending, modifications to existing wastewater treatment facilities, continued imported water deliveries, alternative imported water supplies, desalination, and increased stormwater capture (MWH, 2009a through 2009l; RMC, 2011b; SDLAC, 2012; and CH2MHILL, 2012c). GRIP A and GRIP B were determined to be the best alternatives for implementation and thus, potential water quality impacts for both scenarios were simulated by the SNMP mixing model (refer to Section 7 in the SNMP).

At this time, the GRIP A and GRIP B alternatives are being further evaluated by WRD in terms of feasibility and cost and a Draft Environmental Impact Report (EIR) was issued for public review in March 2014. The Draft EIR (AECOM, 2014) was used as a reference in the preparation of the SED and is available online from the following website: http://www.wrd.org/business/water-replenishment-grip.php. In the Draft EIR, GRIP A was identified as the "proposed project," while GRIP B was identified as an "alternative" to the "proposed project." As a result, it is anticipated that GRIP A likely would be the project to be implemented by WRD. However, this is subject to change until the Final EIR is prepared and certified by WRD.

RW 2A. GRIP Recycled Water Project A (GRIP A) – This planned recycled water project will completely replace imported water used for recharge at the MFSG with a combination of 11,000 AFY of tertiary-treated recycled water produced by SDLAC's San Jose Creek WRP and

10,000 AFY of AWT recycled water produced by a new treatment plant to be constructed by WRD (AECOM, 2014). The tertiary-treated recycled water would be conveyed to the MFSG via an existing underground outfall pipeline. Based on the proposed location of the proposed treatment plant, an underground pipeline is anticipated to be constructed by WRD to convey the AWT recycled water from the proposed treatment plant to the MFSG.

The AWT plant is proposed for construction at either undeveloped areas of SDLAC's San Jose Creek WRP property or on adjacent parcels owned by LADWP and the United States Army Corps of Engineers. If the proposed AWT plant location is revised in the future, the GRIP Draft EIR (AECOM, 2014) will be revised and certified accordingly by WRD. Source water for the proposed AWT plant will consist of tertiary-treated recycled water produced by SDLAC's San Jose Creek WRP. The new AWT plant will include the following treatment processes: microfiltration/ultrafiltration (MF/UF), reverse osmosis (RO), and ultraviolet advanced oxidation process (UV-AOP).

The estimated implementation date for GRIP A is WY 2017-18. Based on the results of the future S/N loading analysis conducted for the SNMP (see Appendix I *Simulated Baseline and Future Salt and Nutrient Groundwater Quality*), implementation of GRIP A will result in similar S/N groundwater quality as from the continued operations of current recharge at the MFSG with the blend of imported water, stormwater, and recycled water.

In the GRIP Draft EIR (AECOM, 2014), GRIP A is identified as the "proposed project," while GRIP B is identified as an "alternative" to the "proposed project." As a result, it is anticipated that GRIP A likely would be the project to be implemented by WRD. However, this is subject to change until the Final EIR is prepared and certified by WRD.

RW 2B. GRIP Recycled Water Project B (GRIP B) – As an alternative to GRIP A, GRIP B would completely replace imported water used for recharge at the MFSG with 21,000 AFY of tertiary-treated recycled water produced by SDLAC's San Jose Creek WRP. Unlike GRIP A, no physical changes to the environment would be required to implement GRIP B since the tertiary-treated recycled water will be conveyed to the MFSG via an existing outfall pipeline. For the SNMP analysis, GRIP B was modeled to begin in WY 2014-15.

Based on the results of the future S/N loading analysis conducted for the SNMP (see Appendix I *Simulated Baseline and Future Salt and Nutrient Groundwater Quality*), implementation of GRIP B will result in slightly higher S/N concentrations in groundwater as compared with the continued operations of current recharge with a blend of imported water, stormwater, and recycled water. However, the SNMP mixing model results indicate that potential impacts from implementation of GRIP B are more than offset by projects that reduce S/N loading in the Central Basin. Thus, average S/N concentrations will not exceed or threaten to exceed their respective BPOs in the Central Basin in the future.

In the GRIP Draft EIR (AECOM, 2014), GRIP B was identified as an "alternative" to GRIP A and thus, was rejected from consideration after the CEQA evaluation (AECOM, 2014). As a result, it is anticipated that GRIP A likely would be the project to be implemented by WRD. However, this is subject to change until the Final EIR is prepared and certified by WRD.

7.3 Non-Potable Recycled Water Reuse Projects

RW 3. Increased Recycled Water Reuse for Irrigation – The Recycled Water Policy encourages the increased use of recycled water as a reliable, drought proof, local, safe source of water supply. Recycled water is utilized for a variety of non-potable reuse (NPR) applications in the CBWCB, including irrigation and industrial operations. For the purposes of the SNMP, irrigation is the primary consideration since it can contribute to S/N loading to the groundwater basins. While recycled water use for irrigation results in increased S/N loading and does not meet the definition of implementation measures, which are projects or programs to control, reduce, or manage (mitigate) S/N loading on a sustainable basis, increased recycled water use is proposed by the CBWCB stakeholders because it is a critical component of the CBWCB water supply sustainability portfolio, meets supports the goals of the Recycled Water Policy, and supports the Governor's recent drought proclamations (see Section 3.3).

As described in Appendix H *Baseline and Future Water Balances*, NPR of recycled water is projected to increase during the SNMP future planning period. Total NPR in the Central Basin is projected to increase from about 9,700 AFY in WY 2009-10 to 22,100 AFY in WY 2014-25. Of this total, recycled water used for irrigation in the Central Basin is projected to increase from about 7,600 AFY in WY 2009-10 to 17,200 AFY in WY 2024-25. In the West Coast Basin, NPR of recycled water is projected to increase from about 21,100 AFY in WY 2009-10 to 44,000 AFY in WY 2024-25. Of this total, recycled water used for irrigation in the West Coast Basin is projected to increase from about 3,900 AFY in WY 2009-10 to 5,800 AFY in WY 2024-25.

As part of the SNMP, the CBWCB stakeholders, in close consultation with the LARWQCB, modeled the impacts on groundwater quality from the increased use of recycled water for irrigation at the average S/N concentrations in the effluent from applicable WRPs during the baseline period (WY 2000-01 through 2009-10). Modeling results show that increased recycled water use for irrigation increases TDS and chloride concentrations in groundwater a very small amount and uses a very small amount of the available assimilative capacity (significantly less than 10%). There was no impact to nutrient (nitrate) loading. Overall, increased recycled water use for irrigation has minimal impacts on groundwater quality and these minor impacts are more than offset by implementation measures and other projects that reduce S/N loading. Groundwater quality in the CBWCB will either continue to improve or remain well below WQOs.

In direct response to California Governor Jerry Brown's April 2014 Executive Order proclaiming a continued state of emergency due to severe drought conditions, the SWRCB adopted *General Waste Discharge Requirements for Recycled Water Use* (General Order No. WQ 2014-0090-DWQ; http://www.waterboards.ca.gov/board_decisions/adopted_orders/water_quality/2014/wqo2014_0090_dwq_revised.pdf) on June 3, 2014 to streamline permitting for recycled water use (i.e. relieve producers, distributors, and users of recycled water from the lengthy permit approval process) throughout the State. This General Order is intended to increase local water supplies by promoting the non-potable use of recycled water in communities grappling with drought conditions. Additionally, the General Order is consistent with the Recycled Water Policy that was adopted by the SWRCB in 2009 and amended in 2013, which required the development of

SNMPs for all groundwater basins in California. Thus, all uses of recycled water allowed by the General Order must be consistent with the SNMPs that will be approved by the Regional Water Quality Control Boards. Importantly, the General Order did not modify existing permitted recycled water quality limits established for irrigation. If this was the case, this would have significantly limited the sustainable and cost effective use of recycled water to offset demand for raw and potable water supplies in the CBWCB.

RW 4. Recycled Water Quality Limits at SMCLs for TDS and Chloride and MCL for Nitrate – Currently, permitted recycled water quality limits established for non-potable reuse (irrigation, industrial and recreational activities) are generally more conservative than the SMCLs established for TDS and chloride. As part of the SNMP, the CBWCB stakeholders, in close consultation with the LARWQCB, modeled the impacts on groundwater quality from the increased use of recycled water for irrigation at the SMCLs for TDS and chloride and at the MCL for nitrate. As discussed further in Section 7.4.1 in the SNMP, the modeling results showed that there were minimal impacts to the basins when utilizing recycled water for irrigation at these concentrations, even at increased volumes. Overall, increased recycled water use for irrigation at the SMCLs for TDS and chloride and MCL for nitrate has minimal impacts on groundwater quality and these minor impacts are more than offset by implementation measures and other projects that reduce S/N loading. Groundwater quality in the CBWCB will either continue to improve or remain well below WQOs. Therefore, the CBWCB stakeholders believe that modification of existing permit levels for recycled water for non-potable reuse are warranted to allow for increased use of recycled water to further reduce dependency on potable water supplies, meet the goals set forth in the Recycled Water Policy to increase the use of recycled water, and more fully embrace the spirit of the Governor's recent drought proclamations, as discussed in Section 3.3.

8 Implementation Plan Challenges

The purpose of this section is to acknowledge the possible technical, institutional, economic, and regulatory challenges that could impact achievement of recycled water and stormwater, goals and objectives, as well as proposed recycled water projects and implementation measures. Accordingly, the implementation plan that will be adopted by the LARWQCB needs to provide flexibility in the event that the implementation schedules for key recycled water projects and implementation measures need to be adjusted to accommodate these challenges. Potential challenges are listed below.

Technical Challenges

- Treatment costs
- Space for treatment facilities
- Space for infrastructure
- Recycled water availability
- Imported water availability
- Stormwater availability

- Seawater barrier injection capacities
- Spreading grounds capacities

Regulatory Challenges

- California Department of Public Health requirements
- LARWQCB requirements
- SWRCB requirements
- United States Environmental Protection Agency requirements
- California Water Code Section 1211 for changes in point or volume of wastewater discharge
- Local requirements and other requirements

Institutional Challenges

- Public acceptance
- Working relationships between water agencies, flood control agencies, groundwater agencies, wastewater management agencies, and municipalities
- Recycled water pricing

Economic Challenges

- Cost of recycled water treatment, conveyance, and brine disposal
- Availability of funding

ACKNOWLEDGMENTS

Many agencies/organizations collaborated to develop the Salt and Nutrient Management Plan (SNMP) and this associated Monitoring Plan for the Central Basin and West Coast Basin (CBWCB). The CBWCB stakeholders would like to recognize and thank everyone who contributed to this tremendous endeavor.

The CBWCB SNMP was made possible by the generous financial support from the Water Replenishment District of Southern California (WRD), Los Angeles County Department of Public Works, West Basin Municipal Water District, Los Angeles Department of Water and Power, and County Sanitation Districts of Los Angeles County. With WRD managing and facilitating the process, these agencies played a key role in every stage of the SNMP development.

Multiple agencies/organizations generously dedicated their time to review and comment on project documents, participate in the stakeholder meetings, and provide vital data for the salt and nutrient analysis. We are especially grateful to the Metropolitan Water District of Southern California, Council for Watershed Health, and City of Los Angeles Bureau of Sanitation for their input and contributions.

We would like to express our gratitude to the Los Angeles Regional Water Quality Control Board and Egoscue Law Group for providing invaluable advice and guidance throughout the entire project.

We are truly thankful to the consultant team indicated below who worked tirelessly to facilitate and prepare the SNMP. We greatly appreciated their expertise and patience.

WY	Water Year

Executive Summary

Two of the most heavily utilized groundwater basins in Southern California are the Central Basin and the West Coast Basin (CBWCB or Study Area), which are located in the southern portion of Los Angeles County. Groundwater in the CBWCB meets approximately a third of the overall water supply needs of nearly 4 million residents and businesses in the 43 cities overlying the basins.

In February 2009, the State Water Resources Control Board (SWRCB) adopted Resolution No. 2009-0011, which established a statewide Recycled Water Policy. The purpose of the Recycled Water Policy is to establish uniform requirements for recycled water use and to develop sustainable water supplies throughout the State, thus encouraging the increased use of recycled water and local stormwater. It also requires development of a Salt and Nutrient Management Plan (SNMP), which should include a Monitoring Plan, for each groundwater basin in California. The SNMP process should be led by local stakeholders, including water and wastewater entities, together with local salt/nutrient contributing stakeholders. For the CBWCB, both the SNMP and the associated *Monitoring Plan* has been submitted to the Los Angeles Regional Water Quality Control Board (LARWQCB) for approval and a Basin Plan Amendment will be prepared by the LARWQCB and subsequently adopted by the LARWQCB Board.

In accordance with the Recycled Water Policy, this *Monitoring Plan* (Plan) for the SNMP was developed through a collaborative process by the CBWCB stakeholders as a means to evaluate concentrations of salt and nutrients (S/Ns) in groundwater with respect to applicable water quality objectives (WQOs). Specifically, this Plan describes the groundwater monitoring program (SNMP Monitoring Program) that was developed to assess total dissolved solids (TDS), chloride, and nitrate, which were determined in the SNMP to be the indicator compounds for S/Ns in the CBWCB. This Plan also summarizes other existing monitoring programs in the CBWCB, as well as special studies that have been conducted or are in progress.

Groundwater in the CBWCB has been and continues to be monitored near recycled water recharge sites, in drinking water wells, and through a large network of multiple completion monitoring wells for many decades. Groundwater from more than 1,500 wells[1] is sampled on a daily to annual basis and hundreds of chemicals/analytical parameters are tested each year. Currently, in significant excess of $1 million is expended annually for just groundwater monitoring and compliance in the CBWCB.

All of the existing groundwater monitoring programs are under direct oversight of regulatory agencies, except for voluntary programs such as the Water Replenishment District of Southern

[1] The total number of wells that are sampled in the CBWCB on a regular basis far exceeds 1,500 because this estimated quantity only includes nested groundwater monitoring wells owned and sampled by WRD, existing production wells, and permit compliance monitoring wells associated with ongoing large recycled water projects in the basins, such as the Montebello Forebay Spreading Grounds and the three seawater intrusion barriers. This quantity does not include the numerous groundwater monitoring wells associated with existing environmental release sites in the CBWCB.

California's (WRD's) Regional Groundwater Monitoring Program (RGWMP). The existing monitoring programs provide a comprehensive and continuing assessment of the overall health of the basins and allow for proper management of S/N loading on a sustainable basis.

Currently, WRD's RGWMP consists of a network of over 300 nested groundwater monitoring wells installed at over 55 locations throughout the CBWCB. Annually, WRD collects nearly 600 groundwater samples from its monitoring well network and analyzes them for over 100 constituents to produce nearly 60,000 individual data points to help track groundwater quality. Because each well is screened in a specific aquifer, constituents including S/Ns are more accurately monitored and can be effectively managed. Each year, WRD publishes a Regional Groundwater Monitoring Report (RGWMR) that provides water quality summary tables (including data for TDS, chloride, and nitrate) for each of the nested wells, water quality maps for the nested wells and production wells, and maps and hydrographs depicting groundwater level data.

The SNMP Monitoring Program was developed based on WRD's RGWMP. Seventy (70) WRD nested groundwater monitoring wells (referred to as the SNMP monitoring wells) at 13 locations throughout the CBWCB have been designated for S/N sampling and reporting as part of the SNMP Monitoring Program. Each well is screened in a specific aquifer, which allows the assessment of S/Ns in all the major aquifers of the CBWCB. These wells were selected based on their location in the most critical areas of the basins, particularly their proximity to water supply wells and groundwater recharge projects that utilize recycled water, including the seawater intrusion barriers (Alamitos Gap Barrier, Dominguez Gap Barrier, and West Coast Basin Barrier) and the Montebello Forebay Spreading Grounds. WRD is the designated entity responsible for collecting TDS, chloride, and nitrate samples (on a semi-annual basis) from the SNMP monitoring wells and submitting this data to the LARWQCB via the SWRCB online GeoTracker database. In addition, WRD's annual RGWMR provides maps depicting chloride, TDS, and nitrate concentrations in the all the nested wells and active drinking water wells, chloride and TDS trend graphs for the SNMP monitoring wells, and a discussion of S/N concentrations/trends in groundwater with respect to WQOs to assess overall groundwater quality in the CBWCB. Thus, both WRD's RGWMP and the SNMP Monitoring Program provide the means for comprehensive assessment and reporting of S/N levels in groundwater in the CBWCB.

In addition to groundwater monitoring, the CBWCB and tributary areas have numerous and extensive monitoring programs for recycled water, wastewater, imported water, and surface water/stormwater, including sampling for chloride, TDS, and nitrate, that are being managed by multiple stakeholder agencies/organizations. The existing and planned augmentation of these monitoring programs, as described in this Plan, are robust and therefore, fully comply with the Recycled Water Policy requirements. The data being collected and reported allow complete characterization of groundwater quality and potential impacts from recycled water projects (e.g. irrigation and groundwater recharge). Further, given the large number of wells monitored, many with depth discrete completions, additional site-specific monitoring at recycled water irrigation sites were not found to be warranted in the CBWCB.

Monitoring for constituents of emerging concern (CECs) in the Study Area is being conducted for groundwater recharge projects that utilize recycled water, wastewater treatment plants that discharge to surface water, and for special studies. There are also ongoing leading edge research efforts to further develop analytical methods and understand the health implications of low level CEC detections. As such, no additional CEC monitoring was found to be warranted in the CBWCB and thus, not proposed as part of the SNMP Monitoring Program.

Based on results from the SNMP Monitoring Program, the SNMP *Monitoring Plan* will be updated as necessary. Additionally, the SNMP *Monitoring Plan* will be reviewed and updated as necessary as part of the SNMP review every 10 years.

1 Introduction

In accordance with the Recycled Water Policy that was issued by the State Water Resources Control Board (SWRCB), this Appendix K describes the *Monitoring Plan* (Plan) that was prepared by Nellor Environmental Associates, Inc. and Todd Groundwater and developed by the stakeholders of the Central Basin and West Coast Basin (CBWCB or Study Area) for the Salt and Nutrient Management Plan (SNMP). These CBWCB stakeholders include the Water Replenishment District of Southern California (WRD), Los Angeles County Department of Public Works (LACDPW), West Basin Municipal Water District (WBMWD), Los Angeles Department of Water and Power (LADWP), County Sanitation Districts of Los Angeles County (SDLAC), Metropolitan Water District of Southern California (MWD), Council for Watershed Health, City of Los Angeles Bureau of Sanitation, and other interested parties. The CBWCB stakeholders also worked collaboratively with the Los Angeles Regional Water Quality Control Board (LARWQCB) to develop the SNMP and this associated *Monitoring Plan*. WRD has been the lead agency managing and facilitating development of the CBWCB SNMP and all associated documents.

Key components of this appendix include a description of the SNMP Monitoring Program and other existing monitoring programs in the CBWCB related to recycled water, wastewater, imported water, surface water/stormwater, and groundwater, including the program origin, responsible agency, monitoring locations, parameters monitored, monitoring frequency, reporting and data location, and quality control/quality assurance information. This Plan also presents information on monitoring and studies related to constituents of emerging concerns (CECs). Attachment K-A consists of a list of definitions related to the SNMP. Attachments K-B through K-P provide more detailed informaton on the different monitoring programs in the CBWCB.

1.1 Regulatory Framework

In February 2009, the SWRCB adopted Resolution No. 2009-0011, *Policy for Water Quality Control for Recycled Water* (Recycled Water Policy). The statewide Recycled Water Policy was revised, specifically the monitoring requirements for priority pollutants and constituents of emerging concern, by an Amendment (Resolution No. 2013-0003) that was adopted by the SWRCB on January 22, 2013 and became effective on April 25, 2013. The Recycled Water Policy and its Amendment (http://www.swrcb.ca.gov/water_issues/programs/water_recycling_policy/docs/rwp_revtoc.pdf) are provided as Appendix A in the SNMP.

The purpose of the Recycled Water Policy is to establish uniform requirements for recycled water used for groundwater recharge and landscape irrigation and to develop sustainable water supplies throughout the State, thus encouraging the increased use of recycled water and local stormwater. It also requires development of a SNMP (which should include a Monitoring Plan) for each groundwater basin in California. The SNMP process should be led by local stakeholders, including water and wastewater entities, together with local salt/nutrient contributing stakeholders. To provide further guidance, on June 28, 2012, the Los Angeles Regional Water Quality Control Board (LARWQCB) issued the *Regional Water Board Assistance* *in Guiding Salt and Nutrient Management Plan Development in the Los Angeles Region* (SNMP Assistance Document), which provides guidance for preparation of SNMPs within the Los Angeles region.

Both the SNMP and this associated *Monitoring Plan* have been submitted to the LARWQCB for approval and subsequently, a Basin Plan Amendment will be prepared by the LARWQCB and adopted by the LARWQCB Board.

1.2 Description of the CBWCB SNMP

The objective of the SNMP is to facilitate basin-wide management of S/Ns from all sources in a manner that optimizes recycled water use while ensuring protection of the groundwater supply and beneficial uses, agricultural beneficial uses, and human health. The SNMP that was developed for the CBWCB identifies total dissolved solids (TDS), chloride, and nitrate to be the indicator compounds for S/Ns. Major elements of the SNMP include the following:

- Goals and Objectives for Stormwater and Recycled Water Use[2]
- Characterization of Hydrogeologic Conceptual Model/Water Quality
- Estimation of Current and Future Salt and Nutrient Loading and Unloading
- A Monitoring Plan
- Estimation of Basin Salt and Nutrient Assimilative Capacity (relative to Water Quality Objectives)
- An Anti-degradation Analysis
- Development of Implementation Measures to Reduce Salt and Nutrient Loading
- California Environmental Quality Act (CEQA) Analysis of the SNMP

After the Recycled Water Policy was issued in 2009, the Water Replenishment District of Southern California (WRD) began coordinating the development of the SNMP for the CBWCB. A stakeholder group was formed, consisting of the WRD (lead agency), LACDPW, WBMWD, LADWP, SDLAC, and MWD. For over 50 years, these agencies as well as other local agencies and numerous cities have been collaborating and implementing critical measures, such as water reclamation and reuse, water conservation, improved maintenance of supply and delivery infrastructure, and the capture and use of stormwater, to prevent overdraft and replenish the CBWCB aquifer system. The use of recycled water in the CWCB has played a vital role in increasing the reliability and sustainability of the overall water supply.

In 2011, the CBWCB stakeholders prepared the *Workplan of the Salt/Nutrient Management Plan, Central Basin and West Coast Basin* (SNMP Workplan) and submitted this document to the LARWQCB for review. The purpose of the SNMP Workplan was to provide an outline of the SNMP and discuss the major elements to be included in the SNMP. On December 13, 2011, LARWQCB issued an approval letter for the SNMP Workplan. This SNMP was prepared in general accordance with the approved SNMP Workplan. Both the SNMP Workplan and the associated LARWQCB approval letter are provided as Appendix D of the SNMP and can be

[2] In addition to goals and objectives for recycled water and stormwater use, all other planned changes impacting salt and nutrient loading and unloading during the future planning period through 2025 in the CBWCB were identified.

downloaded from the LARWQCB website:
http://www.swrcb.ca.gov/rwqcb4/water_issues/programs/salt_and_nutrient_management/Stakeholder_Outreach/Workgroups/central_and_west_coast_Basin.shtml.

At the request of the CBWCB stakeholders, the LARWQCB issued an approval letter to extend the deadline for submittal of the Draft CBWCB SNMP (including this *Monitoring Plan*) and the associated Draft Substitute Environmental Document to LARWQCB for review by August 31, 2014. Based on the SNMP, a Basin Plan Amendment will be subsequently prepared the LARWQCB and adopted by the LARWQCB.

The SNMP is intended to be a living document, and the S/N management program, including the goals, existing basin conditions, implementation measures, SNMP Monitoring Program, etc., will be reviewed every 10 years by the CBWCB stakeholders with revisions made as necessary. However, based on results from the SNMP Monitoring Program, interim updates to the SNMP may be conducted when deemed necessary.

1.3 Background of the Central Basin and West Coast Basin

Two of the most heavily utilized groundwater basins in Southern California are the Central Basin and the West Coast Basin, which are located in the southern portion of Los Angeles County (**Figure K-1**). Groundwater in the CBWCB meets approximately a third of the overall water supply needs of nearly 4 million residents and businesses in the 43 cities overlying the basins.

1.3.1 Physiographic Description

The CBWCB are located in the Coastal Plain of Los Angeles County, California. The Coastal Plain is a northwest-trending structural basin underlain by up to 20,000 feet of sedimentary deposits comprised of gravel, sand, silt, and clay. The major land forms of the Coastal Plain consist of bordering highlands and foothills, older plains and hills, younger alluvial plains, the rivers which drain the area, and the offshore topography. The CBWCB are characterized by a layered aquifer/aquitard system.

The Central Basin covers approximately 280 square miles and extends over most of the Coastal Plain northeast of the Newport-Inglewood Uplift, a series of discontinuous faults and folds that form a prominent line of northwest-trending hills including the Baldwin Hills, Dominguez Hills, and Signal Hill (Figure K-1). It is bounded on the north by the Hollywood Basin, on the northeast by a series of low hills, on the southwest by the Newport-Inglewood Uplift, and on the southeast by the Los Angeles-Orange County line and the Coastal Plain of Orange County.

The Central Basin is geologically divided into four areas: the Los Angeles Forebay, Montebello Forebay, Whittier Area, and Pressure Area (California Department of Water Resources [DWR], 1961). The forebays are areas where confining layers are thin or absent and infiltration of precipitation and surface water can recharge deeper potable production aquifers. The Whittier Area was historically considered a separate basin based on the low lying hills that bound the area to the south, but is now treated as part of the Central Basin. The Central Basin Pressure Area, largest of the four divisions, is characterized by aquifers that are confined by relatively impermeable clay layers over most of the area. The groundwater basin is generally unconfined in the forebays and confined in the pressure area.

The West Coast Basin covers approximately 140 square miles and is bounded by the Newport-Inglewood Uplift on the northeast, by the Santa Monica Basin on the north, and by the Pacific Ocean, Palos Verdes Hills, and the Los Angeles-Orange County line on the southwest and south. Aquifers are generally confined in the West Coast Basin and receive the majority of their natural replenishment from adjacent groundwater basins or from the Pacific Ocean (seawater intrusion). Groundwater flows between the Central Basin and the West Coast Basin based on the groundwater elevations on either side of the Newport-Inglewood Uplift. Most of the groundwater in the CBWCB remains at elevations below sea level, so the importance of maintaining the seawater barrier wells (see Section 1.3.2) to keep out the intruding saltwater is of vital importance.

1.3.2 Groundwater Quality and Replenishment

Between 1900 and the 1950s, groundwater was an important factor in accelerating the urbanization of the CBWCB, which led to increasing demand for groundwater that far exceeded natural freshwater recharge. Over-pumping during this period caused the potentiometric surface[3] to drop to about 100 feet below sea level resulting in seawater intrusion that contaminated coastal aquifers and threatened the future usability of the basins. To remedy the groundwater problems related to supply and quality, multiple salinity and nutrient management measures, which involve the use of recycled water and stormwater, were implemented beginning in the 1950s and continue today.

To reduce the demand on groundwater (thereby reducing drawdown and minimizing the rate of seawater intrusion) and to supplement the water supply, surface water was imported to the region from northern California and the Colorado River via aqueducts. The basins were adjudicated in the 1960s, which limited pumping. Managed aquifer recharge utilizing captured stormwater has been conducted in the northeastern region of the Central Basin since 1938, when the Rio Hondo and San Gabriel River spreading grounds were established by the Los Angeles County Flood Control District (LACFCD). In addition to stormwater, imported water (since 1953) and recycled water (since 1962) are also sources of recharge water at the spreading grounds and there are current plans to potentially deliver advanced treated recycled water (i.e. treatment by reverse osmosis) to the spreading grounds in the near future.

To directly halt seawater intrusion, three barriers (West Coast Basin Seawater Intrusion Barrier, Alamitos Gap Seawater Intrusion Barrier, and Dominguez Gap Seawater Intrusion Barrier) consisting of an extensive network of injection and observation wells were constructed along the coast by the LACFCD between the 1950s and 1970s. Currently, imported water and advanced treated recycled water are utilized for injection at all three barriers. To remediate the saline plume that had been trapped inland due to operation of the West Coast Basin Seawater Intrusion Barrier, two reverse osmosis treatment plants (i.e., desalter facilities) began operating in 1993 and 2002 to pump and treat brackish groundwater for potable supply.

---

[3] A hypothetical surface representing the level to which groundwater would rise if not trapped in a confined aquifer (an aquifer in which the water is under pressure because of an impermeable layer above it that keeps it from seeking its level). The potentiometric surface is equivalent to the water table in an unconfined aquifer.

Groundwater recharge to the CBWCB can occur through underflow from adjacent groundwater basins (such as the Main San Gabriel Basin and the Santa Monica Basin), the Montebello Forebay Spreading Grounds, the seawater intrusion barriers along the coast, precipitation infiltration, return flow of irrigation water that penetrates below the root zone, percolation through unlined river channels, and minor continued seawater intrusion in certain areas. There are currently over 400 active production wells in the basins and groundwater leaves the CBWCB mainly through groundwater extraction. Due to continued pumping depressions, very little groundwater leaves the SBWCB as subsurface outflow.

Groundwater quality in the CBWCB also reflects current and historic land uses. There are localized areas of marginal to poor groundwater quality that are not used for water supply due to shallow depths or that may require treatment prior to use. Historic agricultural activities may have impacted groundwater quality locally and, as a highly urban region, commercial and industrial activities (e.g., leaking aboveground and underground storage tanks, leaking sewer and oil pipelines, and illegal discharges) have contaminated groundwater with localized plumes of petroleum fuels, solvents, and other hazardous substances. In general, these plumes are limited to shallow groundwater. However, as the aquifers and confining layers in these alluvial basins are typically interfingered, the quality of groundwater in the deeper production aquifers can be threatened by the migration of pollutants from the upper aquifers. Overall, the groundwater in the CBWCB continues to be of high quality, suitable for potable and non-potable uses, and continues to meet regulatory requirements.

2 SNMP Monitoring Program

2.1 Recycled Water Policy Requirements

The SWRCB Recycled Water Policy states that the SNMP should include a monitoring program that consists of a network of groundwater monitoring locations *". . . adequate to provide a reasonable, cost-effective means of determining whether the concentrations of salts, nutrients, and other constituents of concern as identified in the salt and nutrient plans are consistent with applicable water quality objectives.*" Additionally, the SNMP monitoring program *". . . must focus on basin water quality near water supply wells and areas proximate to large water recycling projects, particularly groundwater recharge projects. Also, monitoring locations shall, where appropriate, target groundwater and surface waters where groundwater has connectivity with the adjacent surface waters.*" The preferred approach is to *". . . collect samples from existing wells if feasible as long as the existing wells are located appropriately to determine water quality throughout the most critical areas of the basin."* (SWRCB, 2009).

"The SNMP Monitoring Plan shall identify those stakeholders responsible for conducting, sampling, and reporting the monitoring data. The data shall be reported to the Regional Water Quality Control Board at least every three years." With regards to constituents of emerging concern (CECs), the Recycled Water Policy requires that the SNMP include *". . . a provision for annual monitoring of Emerging Constituents/Chemicals of Emerging Concern (e.g., endocrine disruptors, personal care products or pharmaceuticals) consistent with recommendations by CDPH* [now the SWRCB Division of Drinking Water] *and consistent with any actions by the State Water Board* [SWRCB] . . . ." (SWRCB, 2009).

In accordance with the Recycled Water Policy, an SNMP Monitoring Program that was developed for the CBWCB is presented in Section 2.2 below. Section 4 of this Plan addresses CEC monitoring in the CBWCB, including the identification of the CECs monitored and performance measures for salt and nutrient management.

2.2 Description of the SNMP Monitoring Program

As the groundwater manager of the CBWCB, WRD has been monitoring the aquifers in these two basins for over 50 years. Through its Regional Groundwater Monitoring Program (RGWMP), WRD has installed nested groundwater monitoring wells and conducts well sampling, groundwater level monitoring, modeling, and data evaluation continuously to ensure the long-term viability of groundwater in the CBWCB. Currently, the RGWMP consists of a network of over 300 nested groundwater monitoring wells installed at over 55 locations throughout the CBWCB. Each year, WRD publishes a Regional Groundwater Monitoring Report (RGWMR) that provides water quality summary tables (including data for TDS, chloride, and nitrate) for each of the nested wells, water quality maps for the nested wells and production wells, and maps and hydrographs depicting groundwater level data. Further details regarding the RGWMP are provided in Section 3.6.1.

The SNMP Monitoring Program was developed based on WRD's RGWMP. Seventy (70) WRD nested groundwater monitoring wells (now referred to as SNMP monitoring wells) at 13 key locations throughout the CBWCB have been designated for S/N sampling and reporting as part of the SNMP Monitoring Program. Each well is screened in a specific aquifer, which allows the assessment of S/Ns in all the major aquifers of the CBWCB. These wells were selected based on their location in the most critical areas of the basins, particularly their proximity to water supply wells and groundwater recharge projects that utilize recycled water, including the seawater intrusion barriers and the Montebello Forebay Spreading Grounds.

As previously mentioned, TDS, chloride and nitrate were identified in the SNMP as the indicator constituents for S/Ns. Data for these specific constituents that are collected from the SNMP monitoring wells will be uploaded at least annually by WRD to SWRCB's online GeoTracker database. The SNMP Monitoring Program is summarized in **Table K-1** and construction details and the rationale for the locations of the SNMP groundwater monitoring wells are provided in **Table K-2**. All the SNMP nested groundwater monitoring wells are shown in **Figure K-2**.

<tr><td>Reporting / Databases</td><td>• At least annually, WRD will upload TDS, chloride, and nitrate data collected from the SNMP monitoring wells to the SWRCB online GeoTracker database: http://geotracker.waterboards.ca.gov/</td></tr>
</table>

	• WRD's annual Regional Groundwater Monitoring Report (RGWMR), which provides maps depicting chloride, TDS, and nitrate concentrations in all the RGWMP wells and active drinking water wells, chloride and TDS trend graphs for the SNMP monitoring wells, and a discussion of S/N concentrations/trends in groundwater with respect to Water Quality Objectives (WQOs) established in the Basin Plan to assess overall groundwater quality in the CBWCB. The RGWMR is sent to the CBWCB water purveyors and can be downloaded from the WRD website: http://www.wrd.org/engineering/groundwater-engineering-reports.php • WRD's online Geographical Information System (GIS) database provides groundwater quality data, well locations, well construction, and water levels for active production wells and all the RGWMP wells: http://gis.wrd.org/wrdmap/login.asp
Quality Assurance / Quality Control (QA/QC) Program	• Certified laboratories • Field blanks and blind duplicates; unusual analytical results are noted and compared to historical values/trends and if the result appears to be an outlier or anomaly, the result is flagged in the WRD database • Laboratory method blanks, control standards, matrix spike/matrix spike duplicates, and surrogate spikes • Eurofins Eaton Analytical, Inc. and other commercial laboratories: Comprehensive, written QA/QC program (see Attachment K-N)
Compliance Oversight	TDS, chloride, and nitrate data collected from the SNMP monitoring wells will be reviewed by WRD and LARWQCB

Table K-2 Well Construction Details and Location Rationale for SNMP Monitoring Wells

WRD Nested Groundwater Monitoring Well Name	Explanation for Selection of this Well Location for Salt and Nutrient Monitoring	Zone [a]	WRD ID Number	Depth of Well (feet bgs)	Top of Perforation (feet bgs)	Bottom of Perforation (feet bgs)	Aquifer Designation	Model Layer

bgs – below ground surface
a – WRD depth designation

To further assess S/Ns in groundwater, WRD's annual RGWMR provides maps depicting chloride, TDS, and nitrate concentrations in the all the nested wells and active production wells, chloride and TDS trend graphs for the SNMP monitoring wells, and a discussion of S/N concentrations/trends in groundwater with respect to Water Quality Objectives (WQOs) established in the Basin Plan to assess overall groundwater quality in the CBWCB. Thus, both WRD's RGWMP and the SNMP Monitoring Program provide the means for the assessment and reporting of S/N levels in groundwater in the CBWCB.

In addition to groundwater monitoring, the CBWCB and tributary areas have numerous and extensive monitoring programs for recycled water, wastewater, imported water, and surface water/stormwater, including sampling for the three S/N indicators, as discussed further in Section 3. In addition, hundreds of chemicals/analytical parameters, including CECs, are tested each year for multiple source waters. Monitoring for CECs in the Study Area is being conducted for the groundwater recharge projects that utilize recycled water, wastewater treatment plants that discharge to surface water, and for special studies, as discussed further in Section 4.

2.3 Implementation of the SNMP Monitoring Program

Once the LARWQCB has approved the SNMP *Monitoring Plan* and established a GeoTracker weblink for the SNMP Monitoring Program for the CBWCB, WRD will implement the SNMP Monitoring Program by collecting TDS, chloride, and nitrate data from the 70 SNMP monitoring wells on a semi-annual basis and uploading this water quality data to the GeoTracker database.

As discussed earlier, WRD will continue to monitor for salt, nutrients, and other constituents in groundwater as part of its RGWMP and these monitoring results will be presented and evaluated in the annual RGWMR that is issued by WRD. Refer to Section 3.6.1 for a further description of the RGWMP.

2.4 Model Layers and the SNMP Mixing Model

In 2003, the United States Geological Survey (USGS) developed a regional groundwater flow (MODFLOW) model of the CBWCB based on review of geophysical logs along with ancillary information. As part of this groundwater model, the USGS simplified the DWR-defined aquifers into four aquifer systems for modeling purposes. The aquifers were grouped into the Recent (Model Layer 1), Lakewood (Model Layer 2), Upper San Pedro (Model Layer 3), and Lower San Pedro (Model Layer 4). These model layers are used throughout the SNMP to describe the movement and quality of groundwater. The USGS-designated aquifer systems and model layers as they relate to the DWR-designated aquifers are described further in Appendix G *Hydrogeologic Conceptual Model and Existing Salt and Nutrient Groundwater Quality* of the SNMP.

Figure K-3 and Table K-2 indicate the Model Layer that each SNMP monitoring well is screened within. As shown in Figure K-3, Model Layer 1, comprised of the Semi-Perched Aquifer and Gaspur Aquifer, does not exist in all areas of the CBWCB. In the Los Angeles Forebay, the Gaspur Aquifer is typically unsaturated. As a result, there are no monitoring or production wells screened in Model Layer 1 in the Los Angeles Forebay. Model Layer 1 extends to a very small extent into the Whittier Area. As in the Los Angeles Forebay, there are no monitoring or production wells screened in Model Layer 1 in the Whittier Area. Because of its limited extent in the Whittier Area, unsaturated condition in the Los Angeles Forebay, and lack of monitoring data in both areas, Model Layer 1 was not considered as part of the hydrogeologic conceptual model for the Los Angeles Forebay and Whittier Area for the SNMP water quality analysis. This assumption had almost no effect on the estimation of average groundwater quality because Model Layer 1 is very thin and contains a very small volume of water relative to the other model layers. Similarly, Model Layer 1 does not exist in other portions of the Central Basin Pressure Area and West Coast Basin as shown in Figure K-3. In areas where Model Layer 1 does not exist, is unsaturated, or is of very limited extent, S/N loading was assumed to be directly into Model Layer 2.

An SNMP mixing model was developed to simulate/estimate future planning period groundwater quality and evaluate the effects of planned future projects on overall groundwater quality and use of assimilative capacity in the CBWCB through Water Year (WY) 2024-25. The mixing model was developed in Microsoft Excel™ and is effectively a set of linked spreadsheets used to represent "continuously-stirred" mixing volumes (basin/subarea/layer). The mixing model was designed to: 1) account for the current groundwater volume and S/N mass in storage within the CBWCB, and 2) track the loading/unloading of S/Ns through major groundwater sources and sinks under current (baseline period) and future land use/water use conditions (various scenarios for the future planning period).

SNMP mixing model results were calibrated to baseline period (WY 2000-01 through 2009-10) to address the uncertainty in estimating S/N loading for each individual S/N source, identify S/N loading factors with the highest level of significance, and of those factors, modify the ones with the highest level of uncertainty to provide a reasonable match between observed and simulated concentrations. As further described in Appendix I of the SNMP, the following adjustments to key S/N loading estimates were incorporated into the final calibrated mixing model:

- Loading factor for TDS and chloride in irrigation return flows,
- Attenuation factor for nitrate in irrigation return flows throughout the CBWCB,
- Attenuation factor for nitrate for groundwater recharge within the Montebello Forebay, and
- Assumed TDS and chloride concentrations for precipitation return flows.

The SNMP mixing model, as well as model calibration and modeling assumptions, are further described in Appendix I *Simulated Baseline and Future Salt and Nutrient Groundwater Quality* of the SNMP.

3 Existing Monitoring Programs in the CBWCB

Monitoring Program Objectives

- Provide a comprehensive overview of all existing water quality monitoring programs in the Study Area
- Identify any data gaps
- Characterize the CEC monitoring programs

Numerous monitoring programs already exist in the CBWCB and tributary areas. These programs are managed by multiple stakeholder agencies and routinely monitor groundwater, untreated and treated imported water, stormwater/surface water, recycled water, and wastewater. Some programs, such as stormwater/surface water and wastewater monitoring, are part of National Pollutant Discharge Elimination System (NPDES) permits, including regional watershed monitoring programs. Permits issued by the SWRCB Division of Drinking Water (formerly California Department of Public Health) to community water systems mandate monitoring of imported water and production wells. Recycled water monitoring is required as part of permits issued for non-potable reuse projects, as well as groundwater recharge projects that utilize recycled water. Groundwater monitoring for the Montebello Forebay Groundwater Recharge Project and the seawater intrusion barriers (Alamitos Gap Barrier, Dominguez Gap Barrier, and West Coast Basin Barrier) is required as part of each project's waste discharge/water recycling/water reclamation permit. Multiple monitoring wells are utilized to monitor groundwater near the major groundwater recharge projects.

Through its RGWMP, WRD monitors groundwater regionally through a network of nested monitoring wells. WRD reports on groundwater quality and groundwater level trends in annual reports (RGWMR) and is the designated groundwater monitoring entity for the CBWCB under the California Statewide Groundwater Elevation Monitoring (CASGEM) program. Many constituents of concern associated with groundwater contaminated sites are monitored under the oversight of the LARWQCB, the California Department of Toxic Substances Control (DTSC), and the United States Environmental Protection Agency (USEPA). Agencies have also conducted special studies or research that collect various water quality data, including CECs.

Table K-3 summarizes the existing water quality monitoring programs in the CBWCB. The following subsections describe these existing water quality monitoring programs, including responsible agencies, media monitored, monitoring points and locations, constituents monitored, monitoring frequency, quality assurance/quality control (QA/QC) programs, and reporting/data locations. Particular attention is directed at monitoring for the three indicators of salt and nutrients (TDS, chloride, and nitrate) in the CBWCB and CECs (see Section 4). Additional information on water sources and water quality is presented in the SNMP.

3.1 Recycled Water Monitoring for Groundwater Recharge Projects

Recycled water monitoring is conducted for four groundwater recharge reuse projects in the Study Area:

- Montebello Forebay Groundwater Recharge (MFGWR) Project;
- Alamitos Gap Seawater Intrusion Barrier Project (AGB);

Table K-3 Summary of Existing Water Quality Monitoring Programs in the CBWCB

Project	Groundwater Basin	Monitoring Locations	Constituents Monitored	Frequency	Responsible Agency	Reporting
RECYCLED WATER						
Montebello Forebay Groundwater Recharge Project	Central Basin	3 Water reclamation plants (WRPs): Pomona WRP, San Jose Creek WRP, and Whittier Narrows WRP	Salt and nutrients (S/Ns, i.e. total dissolved solids [TDS], chloride, nitrate), general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Daily to quarterly	County Sanitation Districts of Los Angeles County (SDLAC)	Monthly and annual reports submitted to the Los Angeles Regional Water Quality Control Board (LARWQCB) and State Water Resources Control Board (SWRCB), Division of Drinking Water (formerly California Department of Public Health[CDPH]) and posted on the SWRCB online GeoTracker database: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100001790
Alamitos Gap Barrier Seawater Intrusion Barrier	Central Basin and Orange County Basin	1 Advanced water recycling facility: Leo J. Vander Lans Advanced Water Treatment Facility	S/Ns (TDS, chloride, nitrate), Constituents of Emerging Concern (CECs), general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Daily to annually	Water Replenishment District of Southern California (WRD)	Quarterly and annual reports submitted to LARWQCB and the SWRCB Division of Drinking Water (formerly CDPH) and posted on the SWRCB GeoTracker online database: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100006793

Project	Groundwater Basin	Monitoring Locations	Constituents Monitored	Frequency	Responsible Agency	Reporting
RECYCLED WATER						
Dominguez Gap Seawater Intrusion Barrier	West Coast Basin	1 Advanced water recycling facility: Terminal Island Water Reclamation Plant/Advanced Water Purification Facility (TIWRP)	S/Ns (TDS, chloride, nitrate), CECs, general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Daily to annually	City of Los Angeles	Quarterly and annual reports submitted to LARWQCB and the SWRCB Division of Drinking Water (formerly CDPH) and posted on the SWRCB GeoTracker online database: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100000534
West Coast Basin Seawater Intrusion Barrier	West Coast Basin	1 Advanced water recycling facility: Edward C. Little Water Recycling Facility	S/Ns (TDS, chloride, nitrate), CECs, general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Daily to annually	West Basin Municipal Water District (WBMWD)	Quarterly and annual reports submitted to LARWQCB and the SWRCB Division of Drinking Water (formerly CDPH) and posted on the SWRCB GeoTracker online database: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100000047
City of Los Angeles Non-Potable Reuse Program	West Coast Basin	1 Water recycling facility: Terminal Island Water Reclamation Plant/Advanced Water Purification Facility (TIWRP)	S/Ns (TDS, chloride, nitrate), general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Daily to annually	City of Los Angeles	Quarterly and annual reports submitted to LARWQCB and the SWRCB Division of Drinking Water (formerly CDPH) and posted on the SWRCB GeoTracker online database: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100001170

Project	Groundwater Basin	Monitoring Locations	Constituents Monitored	Frequency	Responsible Agency	Reporting
RECYCLED WATER						
WBMWD Nonpotable Reuse Program	West Coast Basin	1 Water recycling facility: Edward C. Little Water Recycling Facility	S/Ns (TDS, chloride, nitrate), general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Daily to annually	West Basin Municipal Water District (WBMWD	Quarterly and annual reports submitted to LARWQCB and the SWRCB Division of Drinking Water (formerly CDPH)

Project	Groundwater Basin	Monitoring Locations	Constituents Monitored	Frequency	Responsible Agency	Reporting
RECYCLED WATER						
SDLAC Nonpotable Reuse Program	Throughout Central Basin and West Coast Basin (CBWCB)	5 Water reclamation plants (WRPs): Pomona WRP, San Jose Creek WRP, Los Coyotes WRP, Long Beach WRP, and Whittier Narrows WRP	S/Ns (TDS, chloride, nitrate), general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Daily to semi-annually	County Sanitation Districts of Los Angeles County (SDLAC)	Quarterly and annual reports submitted to LARWQCB and the SWRCB Division of Drinking Water (formerly CDPH) and posted on the SWRCB GeoTracker online database: • Pomona Water Reclamation Plant (WRP): http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100001746 • San Jose Creek WRP: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100001083 • Los Coyotes WRP: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100001745 • Long Beach WRP: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100001744 • Whittier Narrows WRP: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100001741

Project	Groundwater Basin	Monitoring Locations	Constituents Monitored	Frequency	Responsible Agency	Reporting
WASTEWATER						
SDLAC National Pollutant Discharge Elimination System (NPDES) Permits	Throughout Central Basin	5 Water reclamation plants (WRPs): Pomona WRP, San Jose Creek WRP, Los Coyotes WRP, Long Beach WRP, and Whittier Narrows WRP	S/Ns (TDS, chloride, nitrate), CECs, general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Daily to biennially	County Sanitation Districts of Los Angeles County (SDLAC)	Monthly and annual reports submitted to LARWQCB and posted on the SWRCB online California Integrated Water Quality System (CIWQS) database: http://ciwqs.waterboards.ca.gov/ciwqs/readOnly/PublicReportEsmrAtGlanceServlet?inCommand=reset
IMPORTED WATER						
Untreated Water Imported from Colorado River and State Water Project	Throughout Central Basin and West Coast Basin (CBWCB)	Untreated water delivered to 2 reservoirs: Lake Mathews and Silverwood Lake	S/Ns (TDS, chloride, nitrate), general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Monthly to annually	Metropolitan Water District of Southern California (MWD)	Laboratory data reported to the SWRCB Division of Drinking Water (formerly CDPH) and can be downloaded from their website: http://www.cdph.ca.gov/certlic/drinkingwater/Pages/EDTlibrary.aspx Annual water quality tables distributed to water purveyors and posted on the MWD website: http://www.mwdh2o.com/mwdh2o/pages/yourwater/wq-report/index.html

Project	Groundwater Basin	Monitoring Locations	Constituents Monitored	Frequency	Responsible Agency	Reporting
IMPORTED WATER						
Treated Water from Colorado River water and State Water Project	Throughout Central Basin and West Coast Basin (CBWCB)	Treated water produced by 3 water treatment plants (WTP): Weymouth WTP, Diemer WTP, and Jensen WTP	S/Ns (TDS, chloride, nitrate), general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Daily to annually	Metropolitan Water District of Southern California (MWD)	Laboratory data is reported to the SWRCB Division of Drinking Water (formerly CDPH) and can be downloaded from their website: http://www.cdph.ca.gov/certlic/drinkingwater/Pages/EDTlibrary.aspx Annual water quality tables distributed to water purveyors and posted on the MWD website: http://www.mwdh2o.com/mwdh2o/pages/yourwater/wq-report/index.html
Treated Los Angeles Aqueduct Water	West Coast Basin	Treated water produced by the Los Angeles Aqueduct Filtration Plant	S/Ns (TDS, chloride, nitrate), general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Daily to annually	Los Angeles Department of Water and Power (LADWP)	Laboratory data is reported to the SWRCB Division of Drinking Water (formerly CDPH) and can be downloaded from their website: http://www.cdph.ca.gov/certlic/drinkingwater/Pages/EDTlibrary.aspx The annual water quality report is posted on the LADWP website: https://www.ladwp.com/ladwp/faces/wcnav_externalId/a-w-anual-wqualty-rprt?_adf.ctrl-state=y63elm854_4&_afrLoop=1047980407298000

Project	Groundwater Basin	Monitoring Locations	Constituents Monitored	Frequency	Responsible Agency	Reporting
SURFACE WATER						
Los Angeles River Watershed Monitoring Program	Central Basin and West Coast Basin (CBWCB)	Multiple surface water monitoring locations within the Los Angeles River Watershed	S/Ns (salinity, chloride, nitrate), general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Monthly to annually depending on monitoring location	Council for Watershed Health and other stakeholders	Annual Reports posted on the Council for Watershed Health website: http://watershedhealth.org/dataandreference/Document.aspx
San Gabriel River Regional Monitoring Program	Central Basin and West Coast Basin (CBWCB)	Multiple surface water monitoring locations within the San Gabriel River Watershed	S/Ns (salinity, chloride, nitrate), general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Monthly to annually depending on monitoring location	Council for Watershed Health and other stakeholders	Annual Reports and State of the River Reports posted on the Council for Watershed Health website: http://watershedhealth.org/dataandreference/Document.aspx
Montebello Forebay Groundwater Recharge Project	Central Basin	2 Intakes to the Rio Hondo and San Gabriel River Spreading Grounds	S/Ns (TDS, chloride, nitrate), general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Quarterly	Sampling conducted by WRD; reporting by County Sanitation Districts of Los Angeles County (SDLAC)	Monthly and annual reports submitted to LARWQCB and the SWRCB Division of Drinking Water (formerly CDPH) and posted on the SWRCB online GeoTracker database: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100001790

Project	Groundwater Basin	Monitoring Locations	Constituents Monitored	Frequency	Responsible Agency	Reporting
SURFACE WATER						
SDLAC NPDES Permits	Central Basin and West Coast Basin (CBWCB)	30 Surface water receiving stations	S/Ns (TDS, chloride, nitrate), general minerals, inorganics, toxicity/pollutants, general physical, organic chemicals, etc.	Monthly to annually	County Sanitation Districts of Los Angeles County (SDLAC)	Monthly and annual reports submitted to LARWQCB and posted on the SWRCB online CIWQS database: http://ciwqs.waterboards.ca.gov/ciwqs/readOnly/PublicReportEsmrAtGlanceServlet?inCommand=reset
Los Angeles County Stormwater Monitoring Program	Central Basin and West Coast Basin (CBWCB)	4 Mass Emission Stations, 6 Tributary Stations, Total Maximum Daily Load Compliance Stations, Stormwater Outfalls, Non-Stormwater Outfalls	S/Ns (TDS, chloride, nitrate), general minerals, inorganics, microbiological parameters, general physical, organic chemicals, etc.	Varies from one time sampling to quarterly depending on sampling location, applicable Total Maximum Daily Load, sampling results	Los Angeles County Flood Control District, the County of Los Angeles, and 84 incorporated cities within the coastal watersheds of Los Angeles County, with the exception of the City of Long Beach	Annual reports posted on Los Angeles County Department of Public Works (LACDPW) website: http://ladpw.org/wmd/npdes/report_directory.cfm Laboratory data posted on LACDPW website: http://ladpw.org/wmd/npdes/wq_data.cfm Annual reports and data submitted to LARWQCB and posted on the LARWQCB website: http://www.swrcb.ca.gov/losangeles/water_issues/programs/stormwater/municipal/los_angeles_ms4/lams4annualreport.shtml

GROUNDWATER						
Regional Groundwater Monitoring Program	Throughout Central Basin and West Coast Basin (CBWCB)	>300 nested monitoring wells at more than 55 locations	S/Ns (TDS, chloride, nitrate), general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Semi-annually	Water Replenishment District of Southern California (WRD)	Annual Regional Groundwater Monitoring Reports distributed to water purveyors and LARWQCB and posted on WRD website: http://www.wrd.org/engineering/groundwater-engineering-reports.php
CDPH Title 22 Drinking Water Well Monitoring Program	Throughout Central Basin and West Coast Basin (CBWCB)	>400 production wells	S/Ns (TDS, chloride, nitrate), general minerals, inorganics, radioactivity, bacteriological parameters, general physical, organic chemicals, etc.	Daily to annually	Well owners	Laboratory data reported to the SWRCB Division of Drinking Water (formerly CDPH) and can be downloaded from their website: http://www.cdph.ca.gov/certlic/drinkingwater/Pages/EDTlibrary.aspx Annual Consumer Confidence Reports issued by the water system to their drinking water customers and to the SWRCB Division of Drinking Water (formerly CDPH)
LACDPW Seawater Intrusion Barriers Chloride Groundwater Monitoring Program	Central Basin and West Coast Basin (CBWCB)	Groundwater monitoring wells adjacent to seawater intrusion barriers: Alamitos Gap Barrier – 194 wells; Dominguez Gap Barrier – 243 wells; West Coast Basin Barrier - 355 wells	Salt (chloride)	Semi-annually to annually	Los Angeles County Department of Public Works (LACDPW)	Annual Alamitos Gap Seawater Intrusion Barrier Reports posted on the LACDPW website: http://ladpw.org/wrd/barriers/ Chloride data from other barriers are available upon request from the Water Resources Division of LACDPW: http://dpw.lacounty.gov/contact/

Project	Groundwater Basin	Monitoring Locations	Constituents Monitored	Frequency	Responsible Agency	Reporting
GROUNDWATER						
Montebello Forebay Groundwater Recharge Project	Central Basin	6 monitoring wells; 19 production wells	S/Ns (TDS, chloride, nitrate), general minerals, inorganics, radioactivity, general physical, organic chemicals, etc.	Bimonthly to semi-annually	Sampling conducted by WRD; reporting by SDLAC	Monthly and annual reports submitted to LARWQCB and the SWRCB Division of Drinking Water (formerly CDPH) and posted on the SWRCB online GeoTracker database: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100001790
Alamitos Gap Seawater Intrusion Barrier	West Coast Basin and Orange County Basin	10 groundwater monitoring wells	S/Ns (TDS, chloride, nitrate), general minerals, inorganics, radioactivity, general physical, organic chemicals, total coliform, etc.	Quarterly to annually	Water Replenishment District of Southern California (WRD)	Quarterly, annual, and 5-year engineering reports submitted to LARWQCB and the SWRCB Division of Drinking Water (formerly CDPH) and posted on the SWRCB online GeoTracker database: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100006793
Dominguez Gap Seawater Intrusion Barrier	West Coast Basin	16 groundwater monitoring wells	S/Ns (TDS, chloride, nitrate), general minerals, inorganics, radioactivity, general physical, organic chemicals, total coliform, etc.	Quarterly to annually	Water Replenishment District of Southern California (WRD)	Quarterly, annual, and 5-year engineering reports submitted to LARWQCB and the SWRCB Division of Drinking Water (formerly CDPH) and posted on the SWRCB online GeoTracker database: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100000534

Project	Groundwater Basin	Monitoring Locations	Constituents Monitored	Frequency	Responsible Agency	Reporting
GROUNDWATER						
West Coast Basin Seawater Intrusion Barrier	West Coast Basin	9 groundwater monitoring wells	S/Ns (TDS, chloride, nitrate), general minerals, inorganics, radioactivity, general physical, organic chemicals, total coliform, etc.	Quarterly to annually	Water Replenishment District of Southern California (WRD)	Quarterly, annual, and 5-year engineering reports submitted to LARWQCB and the SWRCB Division of Drinking Water (formerly CDPH) and posted on the SWRCB online GeoTracker database: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100000047
Environmental Release sites	Throughout Central Basin and West Coast Basin (CBWCB)	Monitoring wells located at multiple sites	Organic chemicals, metals, hydrocarbons, perchlorate, etc., depending on chemicals of concern at each specific environmental release site	Varies by environmental release site	Multiple entities (private and public) under the oversight of the LARWQCB, California Department of Toxic Substances Control (DTSC), or United States Environmental Protection Agency (USEPA)	Reports, laboratory, and well data submitted to LARWQCB and posted on the SWRCB online GeoTracker database: http://geotracker.waterboards.ca Reports submitted to DTSC and posted on the DTSC online EnviroStor database: http://www.envirostor.dtsc.ca.gov/public/ Reports submitted to USEPA and posted on the USEPA Superfund Site website: http://yosemite.epa.gov/r9/sfund/r9sfdocw.nsf/WSOState!OpenView&Start=1&Count=1000&Expand=2.14#2.14

Project	Groundwater Basin	Monitoring Locations	Constituents Monitored	Frequency	Responsible Agency	Reporting
GROUNDWATER						
California Groundwater Ambient Monitoring and Assessment Program (GAMA)	Throughout Central Basin and West Coast Basin (CBWCB)	69 groundwater monitoring wells	S/Ns (TDS, chloride, nitrate)	Varies	State Water Resources Control Board (SWRCB) and United States Geological Survey (USGS)	Data available on the SWRCB online GeoTracker GAMA database: http://www.waterboards.ca.gov/gama/

GAMA – California Groundwater Ambient Monitoring and Assessment Program
CIWQS – California Integrated Water Quality System
LACDPW – Los Angeles County Department of Public Works
LARWQCB – California Regional Water Quality Control Board, Los Angeles Region
NPDES – National Pollutant Discharge Elimination System
S/N – Salt and nutrients
TDS – Total dissolved solids
USGS – United States Geological Survey
WRD – Water Replenishment District of Southern California
CDPH – California Department of Public Health (now the SWRCB Division of Drinking Water)
CBWCB – Central Basin and West Coast Basin
DTSC – California Department of Toxic Substance Control
LADWP – Los Angeles Department of Water and Power
MWD – Metropolitan Water District of Southern California
SDLAC – Sanitation Districts of Los Angeles County
SWRCB – State Water Resources Control Board
USEPA – United States Environmental Protection Agency
WBMWD – West Basin Municipal Water District
WRP – Water Reclamation Plant

- West Coast Basin Seawater Intrusion Barrier (WCBB); and
- Dominquez Gap Seawater Intrusion Barrier (DGB).

The three indicators of salts and nutrients (i.e., TDS, chloride, and nitrate) and other related parameters are highlighted in yellow in the following tables for each project.

3.1.1 Montebello Forebay Groundwater Recharge Project

The Montebello Forebay Spreading Grounds (MFSG), which consist of the Rio Hondo Spreading Grounds and the San Gabriel River Spreading Grounds, are located in the northeastern portion of the Central Basin. The MFSG are owned and operated by the Los Angeles County Department of Public Works (LACDPW). The Sanitation Districts of Los Angeles County (SDLAC) provide tertiary-treated recycled water for surface spreading at the MFSG. This water is produced by three water reclamation plants including the Whittier Narrows Water Reclamation Plant (WRP), San Jose Creek WRP, and Pomona WRP. The WRPs provide primary treatment, nitrification / denitrification (NdN) activated sludge biological treatment, granular media filtration, disinfection, and dechlorination. The San Jose Creek WRP and Pomona WRP use sequential chlorination for disinfection; the Whittier Narrows WRP uses ultraviolet irradiation (UV). Information on recycled water (i.e., WRP effluent) monitoring for the MFGWR Project is presented in **Table K-4.** The locations of the San Jose Creek WRP, Whittier Narrows WRP, and Pomona WRP are shown in **Figure K-4**. Additional details on the recycled water monitoring program are presented in **Attachment K-B**.

Quality Assurance / Quality Control (QA/QC) Program	• Certified laboratories • SDLAC laboratories: Blanks, laboratory control standards, duplicate samples, and fortified samples; calibration standards as required by the analytical methods; trip blanks for the analysis of volatile organic analytes; surrogate standards are added to every sample to monitor the overall performance of the procedure with recoveries compared to established acceptance limits; control limits have been established for both precision and accuracy of the laboratory analyses with specified corrective actions when data are outside the control limits • Commercial laboratories: Must have a written comprehensive QA/QC program • Data are checked for completeness as part of the reporting process
Compliance Oversight	Data are reviewed for compliance and any necessary corrective actions by SDLAC, SWRCB Division of Drinking Water, and LARWQCB

3.1.2 Alamitos Gap Seawater Intrusion Barrier

The AGB is located at the southern end of the Central Basin, specifically at the Los Angeles-Orange County border about two miles inland from the mouth of the San Gabriel River. The AGB is jointly owned by LACDPW and Orange County Water District and is operated/maintained by LACDPW. The AGB, consisting of a series of injection wells, was established in the early 1960s to prevent seawater intrusion and replenish groundwater in both the Central Basin and adjacent Orange County Basin. Historically, the AGB received only treated imported water (supplied by MWD), but began also utilizing AWT recycled water in 2005.

The Leo J. Vander Lans Advanced Water Treatment Facility (Vander Lans AWTF), which is owned by WRD and operated by the Long Beach Water Department, performs advanced water treatment (AWT) of tertiary recycled water supplied by SDLAC's Long Beach WRP. Treatment processes at the Vander Lans AWTF historically consisted of microfiltration (MF), reverse osmosis (RO), and UV. During WY 2014-15, when the Vander Lans AWTF was expanded to produce from 3,360 acre-feet per year (AFY) to 8,960 AFY of AWT recycled water, the treatment train was modified to also include advanced oxidation (AOP) through the addition of UV/peroxide. Thus, AWT recycled water is expected to fully replace imported water for injection at the AGB, with flow projected to increase to 7,200 AFY beginning WY 2014-15. However, minor volumes of treated imported water, supplied by MWD, may be utilized as necessary through the future due to temporary operational and maintenance issues that may be encountered at the Vander Lans AWTF or at the AGB.

Information regarding the monitoring of AWT recycled water (i.e., plant product water from Vander Lans AWTF) is summarized in **Table K-5**. The blended water is monitored for multiple constituents, including TDS, chloride, and total nitrogen, on a weekly basis. The location of the Vander Lans AWTF is provided in Figure K-4. More details on the recycled water monitoring program are presented in **Attachment K-C**.

Table K-5 Alamitos Gap Seawater Intrusion Barrier AWT Recycled Water Quality Monitoring

Program Origin	2005 Permit – Los Angeles Regional Water Quality Control Board (LARWQCB) Order No. R4-2005-0061: http://63.199.216.6/larwqcb_new/permits/permit_display.php?order_no=R4-2005-0061&ci_no=8956&program_id=152914 2006 Permit Amendment – Permit amended by State Water Resources Control Board (SWRCB) Water Quality Order No. 2006-0001: http://www.swrcb.ca.gov/board_decisions/adopted_orders/water_quality/2006/wqo/wqo2006_0001.pdf 2007 Permit Amendment – Monitoring and Reporting Program amended per the California Department of Public Health (CDPH) letter dated March 23, 2007 2012 Permit Amendment – Monitoring and Reporting Program amended by LARWQCB letter dated July 20, 2012 http://geotracker.waterboards.ca.gov/regulators/deliverable_documents/5311355412/Alamitos%20Barrier%20Recycled%20Water%20Proj_Amend%20to%20MRP%2C%20CI%208956_2012-07-20.pdf 2014 Permit Amendment – Permit amended per LARWQCB Order No. 2005-0061-A01: http://63.199.216.6/permits/docs/8956_R4-2005-0061_WDR_amd.pdf 2014 Permit (supersedes all previous permits and amendments) – LARWQCB Order No. R4-2014-0111 issued due to the expansion of WRD's expanded Leo J. Quality Assurance/ Quality Control (QA/QC) Program	• Certified laboratories • Long Beach Water Department Laboratory: Comprehensive, written QA/QC program • Eurofins Eaton Analytical, Inc. and its State-certified subcontractor laboratories: Comprehensive, written QA/QC program • Data are checked for completeness as part of the reporting process
Compliance Oversight	Data are reviewed for compliance and any necessary corrective actions by WRD, SWRCB Division of Drinking Water, and LARWQCB

3.1.3 West Coast Basin Seawater Intrusion Barrier

The WCBB, owned and operated by LACDPW, was established in the mid-1950s along the western coast of the West Coast Basin (WCB) to prevent seawater intrusion and replenish the groundwater basin. Historically, the WCBB received only treated imported water (supplied by MWD), but began also utilizing AWT recycled water in 1995.

The Edward C. Little Water Recycling Facility (WRF), which is owned by West Basin Municipal Water District (WBMWD), produces AWT recycled water utilizing treatment processes that include RO, AOP, and chemical stabilization. The source water to the Edward C. Little WRF is secondary effluent from the City of Los Angeles' Hyperion Wastewater Treatment Plant. Information on monitoring AWT recycled water produced by the Edward C. Little WRF is summarized in **Table K-6**.

Little WRF and distributed for non-potable reuse applications (irrigation, industrial and recreational activities) in the West Coast Basin; see Section 3.2.2 a – It is expected that 100% advanced treated recycled water will be injected at the West Coast Basin Seawater Intrusion Barrier beginning in Water Year 2013-14, so blended water monitoring will be conducted when it is utilized as necessary
Reporting/ Databases	• Quarterly and annual reports submitted to LARWQCB and the State Water Resources Control Board (SWRCB), Division of Drinking Water (formerly California Department of Public Health) • Data and reports are submitted to the SWRCB online GeoTracker database, including groundwater monitoring data in Electronic Data Format, sampling points locational data (latitude and longitude), and monitoring reports in Adobe Acrobat™ format: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100000047
Quality Assurance / Quality Control (QA/QC) Program	• Certified laboratories • As part of the State/Federal certification process, a lab must maintain a current QA/QC plan, current standards of practice for each analytical method, conduct method detection limit studies for each analytical method, and participate in performance evaluation blind check sample studies; in addition, the WBMWD laboratory has its own check sample program for its staff and for contract labs • Trip blanks are only used for volatile organic compounds • Eurofins Eaton Analytical, Inc. and other commercial laboratories: Comprehensive, written QA/QC program
Compliance Oversight	Data are reviewed for compliance and any necessary corrective actions by WBMWD, SWRCB Division of Drinking Water, and LARWQCB

In 2013, the Edward C. Little WRF was expanded from 14,000 AFY to 19,600 AFY and treatment now includes ozonation (O_3). The AWT recycled water is monitored for multiple constituents, including TDS, chloride, and total nitrogen, on a quarterly or biweekly basis. It was anticipated that 100 percent AWT recycled water would be injected at the WCBB beginning in WY 2013-14. However, minor volumes of treated imported water, supplied by MWD, may be utilized as necessary for injection through the future due to temporary operational and maintenance issues that may be encountered at the Edward C. Little WRF or at the WCBB. Blended water monitoring will be conducted as appropriate when it is utilized at the WCBB. The location of WBMWD's Edward C. Little WRF is shown in Figure K-4; and more details on the monitoring program are presented **Attachment K-D**.

3.1.4 Dominguez Gap Seawater Intrusion Barrier

The DGB, owned and operated by LACDPW, was established in the early 1970s at the southern portion of the West Coast Basin to prevent seawater intrusion and replenish the groundwater basin. Historically, the DGB received only treated imported water, but began also utilizing AWT recycled water in 2006.

The Terminal Island Water Reclamation Plant/Advanced Water Purification Facility (TIWRP), which is owned and operated by the City of Los Angeles, performs AWT of tertiary recycled water that is produced at the TIWRP. Tertiary treatment at the TIWRP consists of primary treatment, secondary treatment, and filtration; the advanced water treatment process includes MF, RO, and chlorination. Information on monitoring of AWT recycled water is presented in **Table K-7**.

Compliance Oversight	Data are reviewed for compliance and any necessary corrective actions by the City of Los Angeles, SWRCB Division of Drinking Water, and LARWQCB

The AWT recycled water that is produced by the TIWRP is blended with treated imported water prior to injection at the DGB. The blended water is monitored for multiple constituents, including TDS, chloride, and total nitrogen, on a weekly/biweekly basis. In 2017-18, when expansion of the TIWRP is completed, 100 percent AWT recycled water will be injected at the DGB. The location of the TIWRP is presented in Figure K-4. More details on the monitoring program are presented **Attachment K-E**.

3.2 Recycled Water Monitoring for Nonpotable Reuse Projects

Recycled water monitoring is conducted for non-potable reuse projects in the Study Area by the:

- SDLAC,
- WBMWD, and
- City of Los Angeles.

The three indicators of salts and nutrients (i.e., TDS, chloride, and nitrate) and other related parameters are highlighted in yellow in the following tables for each monitoring program.

3.2.1 SDLAC Non-Potable Reuse Recycled Water Monitoring

There are five WRPs owned and operated by the SDLAC that produce tertiary recycled water for non-potable reuse applications (irrigation, industrial and recreational activities) in the CBWCB: Long Beach WRP, Los Coyotes WRP, Pomona WRP, San Jose Creek WRP, and Whittier Narrows WRP. Information on the monitoring of SDLAC's tertiary recycled water (i.e., the effluent of the WRPs) is presented in **Table K-8**. The locations of these SDLAC WRPs are presented in Figure K-4 and more details on the monitoring program are presented **Attachment K-F**.

3.2.2 WBMWD Non-Potable Reuse Recycled Water Monitoring

The Edward C. Little WRF, owned by WBMWD, produces tertiary recycled water for non-potable reuse applications (irrigation, industrial and recreational activities) in the WCB. As discussed in Section 3.1.3, the Edward C. Little WRF also produces advanced treated recycled water, which is subsequently blended with treated imported water and delivered to the WCBB for injection. Information on monitoring of the tertiary recycled water is presented in **Table K-9**. The location of the Edward C. Little WRF is shown in Figure K-4 and more details on the monitoring program are presented **Attachment K-F**.

Compliance Oversight	Data are reviewed for compliance and any necessary corrective actions by WBMWD, SWRCB Division of Drinking Water, and LARWQCB

3.2.3 City of Los Angeles Non-Potable Reuse Recycled Water Monitoring

As part of the Harbor Water Recycling Project, the City of Los Angeles produces tertiary-treated recycled water at its TIWRP for non-potable applications, including irrigation and industrial and recreational activities in the CBWCB. As discussed in Section 3.1.4, the TIWRP also produces advanced treated recycled water, which is subsequently blended with treated imported water and delivered to the DGB for injection. Details of the monitoring program for the tertiary recycled water are presented in **Table K-10**. The location of the City of Los Angeles' TIWRP is shown in Figure K-4.

3.3 Wastewater National Pollutant Discharge Elimination System Monitoring

NPDES monitoring for wastewater discharges to surface waters is conducted by SDLAC within and upstream of the Study Area for the Long Beach WRP, Los Coyotes WRP, San Jose Creek WRP, Whittier Narrows WRP, and Pomona WRP. No other wastewater treatment plants in the CBWCB discharge to surface water. Information on monitoring programs for each NPDES permit is presented in **Table K-11**; the locations of effluent discharge point monitoring for SDLAC's WRPs are presented in **Figures K-5** through **K-9**; and more details on the programs are presented **Attachment K-G**. The three indicators of salts and nutrients (i.e., TDS, chloride, and nitrate) and other related parameters are highlighted in yellow in the following table.

</table>

Quality Assurance/ Quality Control (QA/QC) Program	• Certified laboratories • SDLAC laboratories: blanks, laboratory control standards, duplicate samples, and fortified samples; calibration standards as required by the analytical methods; trip blanks for the analysis of volatile organic analytes; surrogate standards are added to every sample to monitor the overall performance of the procedure with recoveries compared to established acceptance limits; control limits have been established for both precision and accuracy of the laboratory analyses with specified corrective actions when data are outside the control limits • Commercial laboratories: must have a written comprehensive QA/QC program • Data are checked for completeness as part of the reporting process
Compliance Oversight	Data are reviewed for compliance and any necessary corrective actions by SDLAC and LARWQCB

3.4 Imported Water Monitoring

As discussed in the SNMP, water is imported from different sources to the CBWCB for the water supply (uses include drinking water, irrigation, commercial/industrial activities, etc.) and groundwater replenishment. Water is imported to the CBWCB by MWD, the City of Los Angeles, City of Whittier, Suburban Water Company, California Domestic Water Company, and San Gabriel Valley Water Company. MWD imports water from the Colorado River (CR) and State Water Project (SWP). Untreated imported water is delivered to the Montebello Forebay Spreading Grounds and treated water is injected into the seawater intrusion barriers and used for water supply. LADWP imports water from the Owens Valley-Mono Basin and the treated water is used for water supply. LADWP, the City of Whittier, Suburban Water Company, California Domestic Water Company, and San Gabriel Valley Water Company import groundwater that was extracted from the San Gabriel Basin and is used for water supply in the Study Area.

Water imported by MWD and LADWP for supply and recharge comprises, by far, the largest source of imported water to the Study Area. Groundwater supplied by LADWP, City of Whittier, Suburban Water Company, California Domestic Water Company, and San Gabriel Valley Water Company for drinking water, industrial use, or irrigation are considered to be *de minimus* contributors to the salt/nutrient loading. Groundwater that is utilized as drinking water is monitored per California Code of Regulations, Title 22, as discussed in Section 3.6.4.[4]

This section provides details of the monitoring program for untreated imported water supplied by the MWD and recharged in the Montebello Forebay, treated imported water supplied by the MWD and used for injection at the seawater intrusion barriers and for supply in the Study Area, and imported water provided by LADWP for water supply in the Study Area.

[4] As discussed in the SNMP, the volume of water used for irrigation in the Study Area is estimated to be 40 percent of the total supply of imported water and groundwater, plus the recycled water. Assuming an irrigation return flow percentage of 3.6 percent, approximately 8,900 acre-feet (AF) of water recharges the groundwater basins through irrigation.

3.4.1 Untreated MWD Imported Water

Untreated MWD imported water is delivered to the Montebello Forebay spreading facilities for replenishment. Untreated imported water originates from Silverwood Lake and MWD's Lake Mathews reservoirs. Silverwood Lake contains 100 percent SWP water, while Lake Mathews contains 100 percent CR water. Information on MWD's voluntary and compliance monitoring is presented in **Table K-12**; a copy of the Compliance Monitoring Plan is presented **Attachment K-H** (MWD, 2011). **Figure K-10** shows the locations of the reservoirs. The three indicators of salts and nutrients (i.e., TDS, chloride, and nitrate) for the CBWCB SNMP are highlighted in yellow in the following table.

Quality Assurance/ Quality Control (QA/QC) Program	• Certified laboratories • Comprehensive, written QA/QC program
Compliance Oversight	Data are reviewed for compliance and any necessary corrective actions by MWD and the SWRCB Division of Drinking Water

3.4.2 Treated MWD Imported Water

The imported water used for replenishment at the seawater intrusion barriers is a blend of treated water from the CR and SWP, which is supplied by the MWD's Jensen and Diemer Water Treatment Plants (WTPs). The source water at the Jensen WTP is from the SWP. The source water at the Diemer WTP is from both the CR and SWP. Water from MWD's Jensen, Diemer, and Weymouth WTPs is delivered to the CBWCB for water supply. Information on MWD's voluntary and compliance monitoring is presented in **Table K-13**; the treatment plant locations are shown in Figure K-10; and a copy of the Compliance Monitoring Plan is presented Attachment K-H (MWD, 2011). The three indicators of salts and nutrients (i.e., TDS, chloride, and nitrate) for the CBWCB SNMP are highlighted in yellow in the following table.

3.5 Surface Water Monitoring

Surface water monitoring in the Study Area is comprised of the following programs:

- San Gabriel River Regional Monitoring Program (SGRRMP);
- Los Angeles River Watershed Monitoring Program (LARWMP);
- LACDPW Stormwater Program;
- MFGWR Project;
- SDLAC NPDES Permits; and
- LACDPW Surface Water Flow Monitoring Program.

The three SNMP indicators of salts and nutrients (i.e., TDS, chloride, and nitrate) and related parameters are highlighted in yellow in the following tables for each monitoring program.

3.5.1 San Gabriel River Regional Monitoring Program

Multiple stakeholders, including major NPDES permittees, regulatory and management agencies, and conservation groups, began development of the SGRRMP (http://watershedhealth.org/programsandprojects/sgrrmp.aspx) in 2004. Development of the program was motivated by a permit condition for SDLAC. The multi-level monitoring framework combines probabilistic and targeted sampling for water quality, toxicity, and bio-assessment. The program seeks to increase awareness of issues at the watershed scale and improve the coordination and integration of monitoring efforts for both compliance and ambient conditions. It is a watershed-scale counterpart to existing larger-scale regional monitoring efforts in Southern California that seeks to address questions and concerns about regional conditions and trends (CWH, 2010). Other related programs include: the SWRCB Surface Water Ambient Monitoring Program (SWAMP); http://www.waterboards.ca.gov/water_issues/programs/swamp/), USEPA's Western Environmental Monitoring and Assessment Program (WEMAP); http://www.epa.gov/region9/water/wemap/), and the Stormwater Monitoring Coalition (SMC); http://www.socalsmc.org/). The SGRRMP has incorporated some elements of traditional water quality and biological monitoring that focused on discharge points and extended monitoring throughout the entire watershed.

Information on the SGRRMP is summarized in **Table K-15**; monitoring locations in the Study Area are presented in **Figure K-11**; and more detailed information on the program is presented in **Attachment K-J**.

3.5.2 Los Angeles River Watershed Monitoring Program

The LARWMP (http://watershedhealth.org/programsandprojects/larwmp.aspx) was developed during 2007 by a group of stakeholders that included major NPDES permittees, regulatory and management agencies, and conservation groups. Surface water sampling within the Los Angeles River Watershed was initiated in 2008. The objectives of the program are patterned after the SGRRMP; namely, to increase awareness of the importance of issues at the watershed scale and to improve the coordination and integration of monitoring efforts for both compliance and ambient conditions (CWH, 2010). Coordination has been undertaken with regional efforts underway through other programs, including the SWRCB SWAMP, SMC, and Cleaner Rivers Through Effective Stakeholder TMDLs (CREST); http://dawhois.com/www/crestmdl.org.html).

The LARWMP has incorporated some elements of traditional water quality and biological monitoring that focus around discharge points and extended this to sample the entire watershed. Information on the LARWMP monitoring is presented in **Table K-16**; monitoring locations in the Study Area are presented in Figure K-11; and more detailed information on the program is presented in **Attachment K-K**.

3.5.3 Los Angeles County Stormwater Monitoring Program

For data available through 2012, stormwater monitoring was conducted in accordance with the 2001 LARWQCB Order No. 01-182, which served as the NPDES permit for municipal separate storm sewer system (MS4) discharges for 84 cities and a majority portion of the unincorporated areas of Los Angeles County, with the exception of the City of Long Beach. The City of Long Beach has a separate MS4 NPDES permit.

In December 2012, LARWQCB adopted Order No. R4-2012-0175 to replace Order No. 01-182. The 2012 MS4 Permit allows permittees the flexibility to develop Watershed Management Programs (WMPs) or Enhanced Watershed Management Programs (EWMPs) to implement the requirements of the permit on a watershed scale through customized strategies, control measures, and best management practices. A WMP can be implemented by an individual permittee or can be a collaborative effort among permittees within a watershed. An EWMP assumes collaboration among permittees and other partners within a watershed such as water suppliers. Permittees within the Study Area have elected to participate in individual WMPs, WMPs, or EWMPs (see http://www.swrcb.ca.gov/rwqcb4/water_issues/programs/stormwater/municipal/watershed_management/index.shtml).

To meet the monitoring and reporting requirements in the MS4 permit, permittees that elect to participate in a WMP or EWMP must develop the following: 1) an Integrated Monitoring Program (IMP) that covers the core elements of the monitoring program objectives on a jurisdictional basis; 2) an IMP in conjunction with a WMP; or 3) a Coordinated IMP (CIMP) in conjunction with a WMP or EWMP. An IMP leverages monitoring resources by selecting monitoring locations, parameters, or monitoring strategies that will satisfy multiple monitoring requirements. A CIMP has additional benefits including implementation of monitoring on a watershed basis and thereby allowing permittees to pool resources to achieve monitoring requirements.

For permittee developing WMPs or EWMPs, the pertinent deadlines for the MRP and development of the IMPs and CIMPs are as follows:

- December 28, 2012 - Continue monitoring per requirements of Order No. 01-182 and TMDL compliance monitoring requirements until an IMP and/or CIMP is approved.
- June 28, 2013 - Submit a letter of intent. For each core monitoring element, indicate whether an IMP or CIMP will be developed.
- December 28, 2013 - Submit a draft IMP or CIMP if developing a WMP within a 12-month planning horizon.
- June 28, 2014 - Submit draft IMP or CIMP if developing a WMP within an 18-month planning horizon, or if developing an EWMP.
- 30 Days after approval - Commence monitoring under approved IMP.
- 90 Days after approval - Commence monitoring under approved CIMP.

Concurrent with the development of an IMP or CIMP, or within one year of the effective date of Order No. R4-2012-0175, each permittee must submit a non-storm water outfall-based screening and monitoring program plan that is re-assessed at least once during the term of the permit. Permittees must also continue to contribute monitoring resources to the SGRRMP and LARWMP (both of these programs fund 6 sites per year to contribute to the SMC).

Information on Order R4-2012-0175 presented in **Table K-17** is based on current information known about the program, including Mass Emission Station (MES) and Tributary Station monitoring locations in the Study Area are presented in **Figure K-12**. More detailed information on the program, including information on TMDL compliance monitoring is presented in **Attachment K-L**.

Table K-17 Los Angeles County MS4 Stormwater Quality Monitoring

Program Origin	2001 Permit – Los Angeles Regional Water Quality Control Board (LARWQCB) Order No. 01-182, Monitoring and Reporting Program No. CI-6948, National Pollutant Discharge Elimination System (NPDES) No. CAS004001: http://63.199.216.6/larwqcb_new/permits/docs/6948_01-182_MRP.pdf 2012 Permit (replaced 2001 Permit) – LARWQCB Order No. R4-2012-0175: http://www.swrcb.ca.gov/losangeles/water_issues/programs/stormwater/municipal/index.shtml
Responsible Agency	• Los Angeles County Flood Control District, the County of Los Angeles, and 84 incorporated cities within the coastal watersheds of Los Angeles County, with the exception of the City of Long Beach
Number of Monitoring Points	Receiving water monitoring samples collected from: • Mass Emission Stations (MES): 4

<table>
<tr><td></td><td>

- Tributary Stations: 6/seasonal
- Total Maximum Daily Load (TMDL) Compliance Stations

Order R4-2012-0175:

Stormwater and non-stormwater outfalls to be proposed as part of an Integrated Monitoring Program (IMP) or Coordinated Integrated Monitoring Program (CIMP)

Stormwater outfall monitoring samples collected from:

- Stormwater outfalls
- TMDL monitoring locations

Non-stormwater outfall monitoring samples collected from:

- Non-stormwater outfalls
- TMDL monitoring locations

</td></tr>
<tr><td>Monitoring Locations</td><td>

Parameter[a]	Receiving Water Monitoring Frequency
Flow	Wet weather[b] - at a minimum 3 times per year (except toxicity – 2 per year or per TMDL), including the first significant rain event (predicted ≥ 0.25 inches of rainfall); screening parameters during first year for significant rain event (if the result is above a water quality objective, monitoring continues for that parameter) Dry weather[c] - at a minimum 2 per year or per TMDL; toxicity 1 per year (low flow); screening parameters during first year for significant rain event (if the result is above a water quality objective, monitoring continues for that parameter)
Pollutants with TMDL Waste Load Allocations (WLA) or receiving water limits	
Other pollutants on the Clean Water Act (CWA) Section 303(d) List	
Total Suspended Solids (TSS) and Suspended-Sediment Concentration (SSC) if the receiving water on the CWA Section 303(d) List for sedimentation, siltation or turbidity (for dry weather TSS and hardness if metals are measured)	
Hardness	
pH	
Dissolved Oxygen	
Temperature	
Specific Conductivity	
Toxicity	
Screening Parameters: Nitrate, Chloride, Total Dissolved Solids	
Other Screening Parameters: Bacteria, General Constituents, Metals, Semi Volatile Organic Compounds, Chlorinated Pesticides, Polychlorinated Biphenyls, Organophosphate Pesticides, Herbicides	
Parameter[a]	**Stormwater Outfall Monitoring Frequency**
Flow	At a minimum during wet weather[b] – 3 times per year, including the first significant rain event (predicted ≥ 0.25 inches of rainfall);
Pollutants with a water quality based effluent limit derived from a TMDL WLA	
Other pollutants on the CWA Section 303(d) List	
TSS and SCS if the receiving water on the CWA Section 303(d) List for sedimentation, siltation or turbidity	
Dissolved Oxygen	
pH	
Temperature	
Specific Conductivity	
Pollutants identified in a Toxicity Identification Evaluation (TIE) conducted at the downstream receiving water monitoring station or where the TIE was inconclusive; if the discharge exhibits	

	aquatic toxicity, conduct a TIE	
	Screening Parameters: Nitrate, Chloride, Total Dissolved Solids (if found in the nearest receiving water station above a water quality objective)	
	Other Screening Parameters: Bacteria, General Constituents, Metals, Semi Volatile Organic Compounds, Chlorinated Pesticides, Polychlorinated Biphenyls, Organophosphate Pesticides, Herbicides (if found in the nearest receiving water station above a water quality objective)	
	Parameter	**Non-Stormwater Outfall Monitoring**
	Flow	
	Pollutants with a water quality based effluent limit derived from a TMDL WLA	Assessment and selection of outfalls proposed in the IMP or CIMP Outfalls subject to dry weather TMDLs, monitoring proposed in the IMP or CIMP or TMDL Outfalls not subject to dry weather TMDLs, during first year 4 times and then may be reduced to 2 times per year based on results
	Other pollutants on the CWA Section 303(d) List	
	Pollutants identified in a TIE conducted at the downstream receiving water monitoring station or where the TIE was inconclusive; if the discharge exhibits aquatic toxicity, conduct a TIE	
	Screening Parameters: Nitrate, Chloride, Total Dissolved Solids (if found in the nearest receiving water station above a water quality objective)	
	Other Screening Parameters: Bacteria, General Constituents, Metals, Semi Volatile Organic Compounds, Chlorinated Pesticides, Polychlorinated Biphenyls, Organophosphate Pesticides, Herbicides (if found in the nearest receiving water station above a water quality objective)	

a. More detailed information on specific parameters is presented in Attachment K-L
b. Flow > 20 percent of base flow, an alternative approved in IMP or CIMP, or defined in applicable TMDL
c. Flow < 20 percent of base flow, an alternative approved in IMP or CIMP, or defined in applicable TMDL

Other Media Monitored/ Monitoring Locations	• Shoreline water samples • Trash runoff • Regional freshwater monitoring • Discharges from drinking water supplier distribution systems >100,000 gallons • Discharges from lake dewatering • Special Studies • Best Management Practices effectiveness tracking
Reporting/ Databases	• Annual reports and data submitted to LARWQCB and posted on LARWQCB website: http://www.swrcb.ca.gov/losangeles/water_issues/programs/stormwater/municipal/los_angeles_ms4/lams4annualreport.shtml • Annual stormwater monitoring reports posted on Los Angeles County Department of Public Works (LACDPW) website: http://ladpw.org/wmd/NPDES/report_directory.cfm • Stormwater monitoring data posted on LACDPW website: http://ladpw.org/wmd/npdes/wq_data.cfm
Quality Assurance / Quality Control (QA/QC) Program	• Certified laboratories • Bottle labeling, chain-of-custody tracking, sampler equipment checkout and setup, sample collection, field blanks, field duplicate samples, transportation to the laboratory, field personnel training, laboratory analysis program that includes QA/QC protocols (LACDPW, 2012)
Compliance Oversight	Data are reviewed for compliance and any necessary corrective actions by LACDPW, LARWQCB, Council for Watershed Health, and Southern California Stormwater Monitoring Coalition

3.5.4 Montebello Forebay Groundwater Recharge Project

The quality of surface water entering (i.e., headworks samples) the San Gabriel River and Rio Hondo Spreading Grounds is monitored in accordance with the permit requirements for the MFGWR Project. Information on the MRP is presented in **Table K-18**; monitoring locations are presented in **Figure K-13**; and more detailed information on the program is presented in Attachment K-B.

Table K-18 MFGWR Project Surface Water/Intake Quality Monitoring

Program Origin	1991 Permit – Los Angeles Regional Water Quality Control Board (LARWQCB) Order No. 91-100: http://63.199.216.6/larwqcb_new/permits/permit_display.php?order_no=91-100&ci_no=5728&program_id=4723 2009 Permit Amendment – Permit amended by LARWQCB Order No. R4-2009-0048: http://63.199.216.6/larwqcb_new/permits/permit_display.php?order_no=R4-2009-0048&program_id=4723&ci_no=5728

Compliance Oversight	Data are reviewed for compliance and any necessary corrective actions by SDLAC and LARWQCB

3.5.6 LACDPW Surface Water Flow Monitoring Program

The LACDPW operates a number of stream gauge stations in and tributary to the Study Area. A map and list of the stations are provided in **Attachment K-M**. Stream gauge data are published by the LACDPW in their annual *Hydrologic Reports* (LACDPW, undated) and on their website (http://dpw.lacounty.gov/wrd/report/). The LACDPW uses these gauge stations to help quantify the volume of water actively recharge (i.e., conserved) in Los Angeles County. The LACDPW reports the volumes of surface water recharged in spreading grounds in their annual reports and on their website (http://ladpw.org/wrd/spreadingground/).

3.6 Groundwater Monitoring

Groundwater monitoring is performed for the following programs/projects in the Study Area:

- WRD Regional Groundwater Monitoring Program (RGWMP);
- LACDPW Seawater Intrusion Barriers Chloride Groundwater Monitoring Program;
- Groundwater Recharge Projects, per California Code of Regulations, Title 22, Division 4, Chapter 3, Water Recycling Criteria:
    - MFGWR Project,
    - AGB,
    - WCBB, and
    - DGB;
- California Code of Regulations, Title 22 Drinking Water Well Program;
- SWRCB Groundwater Ambient Monitoring and Assessment Program (GAMA);
- Environmental release sites (mandatory and voluntary programs under the purview of LARWQCB, DTSC, USEPA, and local regulatory agencies); and
- Regional Groundwater Level Monitoring Programs.

Information on each program is presented in the following sections. The three indicators of salts and nutrients (i.e., TDS, chloride, and nitrate) and associated parameters are highlighted in yellow in the following tables for each monitoring program.

3.6.1 WRD Regional Groundwater Monitoring Program

As mentioned in Section 2.2, WRD has been monitoring groundwater in the CBWCB for over 50 years. Through its RGWMP, WRD installs nested groundwater monitoring wells and conducts well sampling, groundwater level monitoring, groundwater modeling, and data evaluation to ensure the long-term viability of groundwater in the CBWCB. This information in turn provides WRD, the pumpers in the basins, other stakeholders, and the public with the knowledge necessary for responsible water resources planning and management. In order to obtain accurate data for specific aquifers from which to infer localized water level (and water quality conditions), depth-specific (nested) monitoring wells that tap discrete aquifer zones are evaluated as part of WRD's regional groundwater monitoring program. Currently, the RGWMP consists of a network of over 300 nested groundwater monitoring wells installed at over 55 locations throughout the CBWCB. Between 2013 and 2014, WRD plans on constructing up to 20 additional nested monitoring wells at three locations in the Study Area, as depicted in **Figure K-14**, to better manage regional groundwater.

Attachment K-N contains a table showing construction information for the WRD nested monitoring wells (over 300 wells) in the CBWCB. Figure K-14 shows the locations of the nested wells and the 13 key nested wells that are designated for assessment of regional groundwater quality and water level trends. The 13 key nested well locations, which consists of a total of 70 depth-specific monitoring wells, have been designated for S/N sampling and reporting as part of the SNMP Monitoring Program. As discussed in Section 2.2, these 70 nested wells are also referred to as the SNMP monitoring wells.

Each year, WRD publishes the annual RGWMR, which provides the results of WRD's current and ongoing regional groundwater monitoring program. The RGWMR provides water quality summary tables (including data for TDS, chloride, nitrate) for each of the nested wells, water quality maps for the nested wells and active drinking water wells, maps and hydrographs depicting groundwater level data, and TDS and chloride trend graphs (see Section 2.2). Water quality data regarding active drinking water wells are provided by the SWRCB Division of Drinking Water (formerly CDPH) through the California Code of Regulations, Title 22 monitoring program (see Section 3.6.4).

In addition to being the groundwater manager for the CBWCB, WRD is the designated groundwater monitoring entity for the CBWCB under the CASGEM program (see Section 3.6.7). As part of WRD's Groundwater Contamination Prevention Program, WRD also tracks the investigations of priority environmental release sites within the CBWCB and works with regulatory agencies to expedite cleanup of these contaminated sites (see Section 3.6.6).

Annually, WRD collects nearly 600 groundwater samples from its monitoring well network and analyzes them for over 100 constituents to produce nearly 60,000 individual data points to help track groundwater quality. Because each nested well is screened in a specific aquifer, constituents including S/Ns are accurately monitored and can be effectively managed. The RGWMP is summarized in **Table K-20** and presented in **Attachment K-N**. Details regarding the regional groundwater level monitoring programs in the CBWCB are discussed in Section 3.6.7.

Table K-20 WRD Regional Groundwater Monitoring Program

Program Origin	Water Replenishment District of Southern California's (WRD's) Regional Groundwater Monitoring Program Plan (see Attachment K-N)
Responsible Agency	WRD
Number of Monitoring Points	>300 nested groundwater monitoring wells at >55 locations throughout the Central Basin and West Coast Basin (CBWCB); of these wells, a total of 70 nested wells at 13 locations are designated as key wells to assess

<table>

b. Evaluations include trend graphs for 70 key nested wells in the CBWCB</td></tr>
<tr><td>Other Media Monitored/ Monitoring Locations</td><td>• Groundwater levels in the nested monitoring wells; see Section 3.6.7
• Assessment of California Code of Regulations, Title 22 monitoring data and groundwater levels for >400 production wells located throughout the CBWCB; see Section 3.6.4</td></tr>
<tr><td>Reporting / Databases</td><td>• Annual Regional Groundwater Monitoring Reports (provides water quality data tables, trend graphs for water levels and various constituents that include total dissolved solids and chloride, water quality concentration maps, and water elevation contour maps) sent to the CBWCB water purveyors and posted on the WRD website for downloading: http://www.wrd.org/engineering/groundwater-engineering-reports.php
• WRD's online Geographical Information System database provides groundwater quality data, well locations, well construction, and water levels for drinking water wells and the nested monitoring wells: http://gis.wrd.org/wrdmap/login.asp</td></tr>
</table>

	• At least annually, WRD will upload TDS, chloride, and nitrate data collected from the SNMP monitoring wells to the SWRCB online GeoTracker database (see Section 2.2): http://geotracker.waterboards.ca.gov/
Quality Assurance / Quality Control (QA/QC) Program	• Certified laboratories • Field blanks and blind duplicates; unusual analytical results are noted and compared to historical values/trends and if the result appears to be an outlier or anomaly, the result is flagged in the WRD database • Laboratory method blanks, control standards, matrix spike/matrix spike duplicates, and surrogate spikes • Eurofins Eaton Analytical, Inc. and other commercial laboratories: Comprehensive, written QA/QC program (see Attachment K-N)
Compliance Oversight	Data are currently reviewed for compliance and any necessary corrective actions by WRD, groundwater pumpers, and the State Water Resources Control Board (SWRCB), Division of Drinking Water (formerly California Department of Public Health)

3.6.2 LACDPW Seawater Intrusion Barriers Chloride Groundwater Quality Monitoring Program

The LACDPW monitors chloride concentrations in groundwater monitoring wells near the AGB, DGB, and WCBB as summarized in **Table K-21**. **Figure K-15** shows the locations of the wells monitored, as well as the barrier injection wells.

Table K-21 LACDPW Seawater Intrusion Barriers Chloride Groundwater Quality Monitoring

Program Origin	Los Angeles County Department of Public Works (LACDPW) and other groundwater stakeholders
Responsible Agency	Los Angeles County Department of Public Works (LACDPW)
Number of Monitoring Points	Groundwater sampling of these monitoring wells in the vicinity of: • Alamitos Gap Seawater Intrusion Barrier (AGB) – 194 wells • West Coast Basin Seawater Intrusion Barrier (WCBB) – 355 wells • Dominguez Gap Seawater Intrusion Barrier (DGB) – 243 wells
Monitoring Locations	Groundwater monitoring wells owned and sampled by LACDPW (see Figure K-15)
Constituents and Frequency	**Parameter**: Chloride — **Monitoring Frequency**: Annual - Semi-annual
Other Media Monitored/ Monitoring Locations	Groundwater levels in monitoring wells owned by Los Angeles County and located throughout the CBWCB; see Section 3.6.7
Reporting / Databases	• Annual Operation Reports for the AGB are posted on the LACDPW website for downloading: http://ladpw.org/wrd/barriers/

	• Data regarding the WCBB and DGB are available upon request from the Water Resources Division of LACDPW: http://dpw.lacounty.gov/contact/
Quality Assurance / Quality Control (QA/QC) Program	• Certified laboratories • Comprehensive, written QA/QC program
Compliance Oversight	Data are reviewed for barrier operation by LACDPW and groundwater stakeholders

3.6.3 Groundwater Recharge Monitoring

3.6.3.1 MFGWR Project Groundwater Quality Monitoring

Information on groundwater monitoring for the MFGWR Program is presented in **Table K-22**; the groundwater monitoring locations are presented in **Figure K-16**; and more details on the groundwater monitoring program are presented in **Attachment K-B**.

Table K-22 MFGWR Project Groundwater Quality Monitoring

Program Origin	1991 Permit – Los Angeles Regional Water Quality Control Board (LARWQCB) Order No. 91-100 Water Recycling Requirements and Monitoring and Reporting Program: http://63.199.216.6/larwqcb_new/permits/docs/5728_91-100_WRR.pdf 2009 Permit Amendment – Permit amended by LARWQCB Order No. R4-2009-0048: http://63.199.216.6/larwqcb_new/permits/docs/5728_R4-2009-0048_WDR_amd.pdf 2012 Permit Amendment – Monitoring and Reporting Program amended by LARWQCB letter dated August 30, 2012: http://63.199.216.6/larwqcb_new/permits/docs/5728_91-100_MRP_amd.pdf 2013 Permit Amendment – LARWQCB letter dated June 4, 2013 approving an increase in the compliance averaging period for recycled water contribution: http://geotracker.waterboards.ca.gov/esi/uploads/geo_report/3643924772/WDR100001790.PDF 2014 Permit Amendment – Permit amended by LARWQCB Order No. R4-2009-0048-A-01, increasing the permitted maximum quantity of recycled water from 35% to 45% of total inflow in any 10-year period: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100001790
Responsible Agency	Sampling conducted by the Water Replenishment District of Southern California (WRD); reporting conducted by the Sanitation Districts of Los Angeles County (SDLAC)
Number of Monitoring Points	Groundwater samples collected by WRD from: • 6 shallow monitoring wells (monitored bimonthly) and • 19 production wells (monitored semiannually)

Monitoring Locations	Shallow monitoring wells and production wells located in proximity to the Montebello Forebay Spreading Grounds (see Figure K-16)
Constituents and Frequency	<table><tr><th>Parameter</th><th>Monitoring Frequency[a]</th></tr><tr><td>Total Dissolved Solids</td><td>Bimonthly - Semi-annually</td></tr><tr><td>Chloride</td><td>Bimonthly - Semi-annually</td></tr><tr><td>Other Major Minerals</td><td>Bimonthly - Semi-annually</td></tr><tr><td>Nitrate</td><td>Bimonthly - Semi-annually</td></tr><tr><td>Other Nitrogen Compounds</td><td>Bimonthly - Semi-annually</td></tr><tr><td>Oxidants & Reductants</td><td>Bimonthly - Semi-annually</td></tr><tr><td>Base/Neutral Extractable Organics</td><td>Bimonthly - Semi-annually</td></tr><tr><td>Acid Extractable Organics</td><td>Bimonthly - Semi-annually</td></tr><tr><td>Pesticides</td><td>Bimonthly - Semi-annually</td></tr><tr><td>Purgeable Organics</td><td>Bimonthly - Semi-annually</td></tr><tr><td>Miscellaneous Organics</td><td>Bimonthly - Semi-annually</td></tr><tr><td>Physical Properties</td><td>Bimonthly - Semi-annually</td></tr><tr><td>Iron and Manganese</td><td>Bimonthly - Semi-annually</td></tr><tr><td>Trace Constituents</td><td>Bimonthly - Semi-annually</td></tr><tr><td>Radioactivity</td><td>Bimonthly - Semi-annually</td></tr></table>a. Shallow wells monitored bimonthly; production wells monitored semiannually
CEC Monitoring	CEC monitoring is currently not required by the permit; however, when the permit is amended in the future, it is expected to include CEC monitoring in accordance with the Recycled Water Policy and State regulations for groundwater replenishment using recycled water (also see CEC research in Section 4)
Other Media Monitored/ Monitoring Locations	• Recycled water (see Sections 3.1 and 3.2); • Surface water for the intake points to the Rio Hondo Spreading Grounds and San Gabriel River Spreading Grounds (see Section 3.5.4)
Reporting/ Databases	• Monthly and annual reports submitted to LARWQCB and the State Water Resources Control Board (SWRCB), Division of Drinking Water (formerly California Department of Public Health) • Data and reports submitted to the SWRCB GeoTracker online database, including groundwater monitoring data in Electronic Data Format, well locational data (latitude and longitude), and monitoring reports in Adobe Acrobat™ format: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100001790
Quality Assurance / Quality Control (QA/QC) Program	• Certified laboratories • Field blanks and blind duplicates; unusual analytical results are noted and compared to historical values/trends and if the result appears to be an outlier or anomaly, the result is flagged in the WRD database • Laboratory method blanks, control standards, matrix spike/matrix spike duplicates, and surrogate spikes • Eurofins Eaton Analytical, Inc. and other commercial laboratories: Comprehensive, written QA/QC program

Compliance Oversight	Data are reviewed for compliance and any necessary corrective actions by WRD, SDLAC, SWRCB Division of Drinking Water, and LARWQCB

3.6.3.2 Alamitos Gap Seawater Intrusion Barrier Groundwater Quality Monitoring

As discussed in Section 3.1.2, the AGB is operated by LACDPW and WRD's Vander Lans AWTF produces the AWT recycled water that is delivered to the AGB for injection. Information on groundwater monitoring associated with the AGB is presented in **Table K-23**; and more details on the groundwater monitoring program are presented in **Attachment K-C**. The AGB groundwater monitoring well locations are shown in **Figure K-17**. WRD currently is pursuing a permit amendment for the current expansion of the Vander Lans AWTF.

Compliance Oversight	Data are reviewed for compliance and any necessary corrective actions by the City of Los Angeles, the SWRCB Division of Drinking Water, and LARWQCB

3.6.4 California Code of Regulations, Title 22 Drinking Water Well Program

The City of Whittier, LADWP, Suburban Water Company, California Domestic Water Company, and San Gabriel Valley Water Company import groundwater that was extracted from the San Gabriel Basin and is used for water supply in the Study Area. This imported groundwater is specifically used for drinking water, industrial activities, and/or irrigation and is considered to be *de minimus* contributors to the salt/nutrient loading. Groundwater that will be utilized as drinking water is regulated under Title 22 of the California Code of Regulations.

The SWRCB Division of Drinking Water (formerly CDPH) regulates public drinking water systems in the State to ensure the delivery of safe drinking water to the public. A public drinking water system is defined as a system for the provision of water for human consumption through pipes or other constructed conveyances that has 15 or more service connections or regularly serves at least 25 individuals daily at least 60 days out of the year. Private domestic wells are not regulated by the SWRCB Division of Drinking Water.

The SWRCB Division of Drinking Water enforces the monitoring requirements established in Title 22 of the California Code of Regulations for drinking water wells and all the data collected must be reported to the SWRCB Division of Drinking Water, as summarized in **Table K-26** below. Title 22 also designates the regulatory limits (e.g., MCLs) for various water contaminants, including volatile organic compounds, non-volatile synthetic organic compounds, inorganic chemicals, radionuclides, disinfection byproducts, general physical constituents, and other parameters.

Table K-26 California Code of Regulations, Title 22 Drinking Water Well Monitoring

Program Origin	Title 22 of the California Code of Regulations: http://www.cdph.ca.gov/certlic/drinkingwater/Pages/Lawbook.aspx
Responsible Agency	Drinking water well owners
Number of Monitoring Points	Groundwater samples from >400 production wells in the Central Basin and West Coast Basin (CBWCB)
Monitoring Locations	Active drinking water wells permitted by the State Water Resources Control Board (SWRCB), Division of Drinking Water (formerly California Department of Public Health) that are located throughout the CBWCB (see Figure K-20)
Constituents and Frequency	Drinking water wells are sampled for many parameters, including coliform bacteria/E-coli, volatile organic compounds, non-volatile synthetic organic compounds, inorganic chemicals, radionuclides, disinfection byproducts, and other general physical constituents The constituents monitored and the frequency of monitoring varies based on the well location, size of the water system, and history of water quality results These programs include the three indicators of salts and nutrients (total dissolved solids, chloride, and nitrate) designated in the Salt & Nutrient Management Plan Drinking water wells must be sampled in accordance with monitoring schedules (http://www.cdph.ca.gov/certlic/drinkingwater/Pages/Monitoring.aspx) enforced by the SWRCB Division of Drinking Water
Other Media Monitored/ Monitoring Locations	Water samples are collected at various locations throughout the distribution system, including: • Service connections to other systems or imported water service connections • Designated sampling points along the distribution piping • Effluent of water storage tanks and blending tanks • Effluent of treatment plants
Reporting/ Databases	• Analytical results are submitted directly to the SWRCB Division of Drinking Water database as Electronic Database Files: http://www.cdph.ca.gov/certlic/drinkingwater/Pages/EDT.aspx • Title 22 monitoring data can be downloaded from the SWRCB Division of Drinking Water website: http://www.cdph.ca.gov/certlic/drinkingwater/Pages/EDTlibrary.aspx • Title 22 monitoring data is also uploaded into the Water Replenishment District of Southern California's (WRD's) online Geographical Information System database, which provides groundwater quality data, well locations, well construction, and water levels for drinking water wells and WRD's nested monitoring wells: http://gis.wrd.org/wrdmap/login.asp
Quality Assurance / Quality Control	• Certified laboratories and their established QA/QC programs • Utilize U.S Environmental Protection Agency method acceptance criteria and laboratory internal controls for QC parameters, including preparation blanks, surrogates, spikes, duplicates and laboratory control samples

(QA/QC) Program	
Compliance Oversight	Data are reviewed for compliance and any necessary corrective actions by groundwater pumpers and the SWRCB Division of Drinking Water

Figure K-20 depicts the drinking water wells with recent (last five years) water quality data in the SWRCB Division of Drinking Water database.

3.6.5 GAMA and USGS Groundwater Monitoring

In 2000, the SWRCB established the GAMA Program, California's comprehensive groundwater quality monitoring program (http://www.swrcb.ca.gov/water_issues/programs/gama/). The main goals of GAMA are to improve statewide groundwater monitoring, increase the availability of groundwater quality information to the public, and better understand and identify risks to groundwater resources. There are currently four components to the GAMA Program:

1. Priority Basin Project – To assess California's drinking water aquifers, the U.S. Geological Survey (USGS) collects groundwater samples from public supply wells throughout the State and analyzes the samples for regulated and unregulated chemicals, including emerging contaminants such as pharmaceuticals and personal care products, isotopes, and age-dating tracers. Monitoring and assessments are on a 10-year cycle, with trend monitoring more frequent. More details on this project can be found at: http://www.swrcb.ca.gov/water_issues/programs/gama/priority_basin_projects.shtml.
2. Domestic Well Project – Private wells in the State are sampled by volunteer well owners and samples are analyzed for nitrate, trace metals, volatile organic compounds, pesticides, and radionuclides.
3. Special Studies Project – With the Lawrence Livermore National Laboratory as the project lead, specific groundwater quality studies have been conducted using state of the art scientific techniques and methods that help researchers and public policy planners to better understand how groundwater contamination occurs and behaves. Studies have included sources of nitrate, wastewater mixing, groundwater recharge, trace detection of pharmaceutical compounds and personal care products, using low-level anthropogenic compounds as tracers, and isotopic composition as a contamination source tool.
4. GeoTracker GAMA – A publicly-accessible, on-line groundwater information system that integrates and displays water quality data on an interactive, searchable map (http://geotracker.waterboards.ca.gov/gama/). Its analytical tools and reporting features help users assess groundwater quality and identify potential groundwater issues. GeoTracker GAMA contains over 125 million data records from different sources such as cleanup sites, well logs, the SWRCB Division of Drinking Water (formerly CDPH) water quality data from public supply wells, water levels from the California Department of Water Resources, California Department of Pesticide Regulation, the GAMA Priority Basin Project, the GAMA Domestic Well Project, and the GAMA Special Studies Project.

As part of the GAMA Priority Basin Project (http://ca.water.usgs.gov/projects/gama/), the USGS collects and analyzes groundwater samples from public supply wells in the CBWCB for:

- Synthetic organic constituents – Includes volatile organic compounds, gasoline oxygenates and their degradates, pesticides, polar pesticides and pesticide degradates, pharmaceutical compounds, and potential wastewater indicators);
- Constituents of special interest – Includes perchlorate, n-nitrosodimethylamine, 1,4-dioxane, and 1,2,3-trichloropropane;
- Inorganic constituents that can occur naturally – Includes nutrients, major and minor ions, and trace elements;
- Radioactive constituents;
- Microbial indicators; and
- Naturally occurring isotopes and dissolved noble gases – Measured to help identify the sources and ages of the sampled groundwater (USGS, 2009).

Data collected by the USGS in the CBWCB as part of the GAMA Priority Basin Project were sent to well owners in July 2007; the Assessment Report was released in September 2012 (Goldwrath et al., 2012).

Quality assurance samples (blanks, replicates, and samples for matrix spikes) are collected by USGS at approximately one-fourth of the wells. In addition, the USGS has conducted other recent groundwater quality studies in the CBWCB to characterize groundwater quality and saline intrusion (USGS, 2003 and 2004).

3.6.6 Environmental Release Sites

In general, groundwater in the main producing aquifers of the CBWCB is of good quality. However, localized areas of marginal to poor quality water does exist, primarily at the basin margins where seawater intrusion occurred in the past and also in shallow groundwater near "environmental release sites." Environmental release sites are commercial and industrial properties where improper activities (e.g., leaking aboveground and underground storage tanks, leaking pipelines, spills, illegal discharges, etc.) have contaminated groundwater with localized plumes of petroleum fuels, solvents, and other hazardous substances. In general, these plumes are predominantly limited to shallow groundwater. However, as the aquifers and confining layers in the CBWCB are typically inter-fingered, the quality of groundwater in the deeper production aquifers is threatened by the migration of pollutants from the upper aquifers. This is particularly true in the forebay areas.

Thousands of environmental release sites in the CBWCB are actively investigated, monitored, and remediated under existing programs managed by the LARWQCB, DTSC, USEPA, and local regulatory agencies. In addition, voluntary monitoring and investigations are conducted at some contaminated sites. At many of these contaminated sites, groundwater monitoring wells have been installed and samples are collected on a regular basis and results are reported to the lead regulatory agency.

Figure K-21 shows all active and inactive environmental release sites in the Study Area including land disposal sites, military sites, cleanup program sites, and active or proposed Superfund sites. Active sites are properties currently being investigated or cleaned up under regulatory agency review or oversight. Inactive sites are cases that have been closed by the relevant regulatory agency. For Superfund sites and active land disposal sites indicated in Figure 21, call-out boxes show the name of the site and the main constituents of concern (COCs).

Chemicals commonly associated with the environmental release sites in the CBWCB are trichloroethylene (TCE), tetrachloroethylene (PCE), metals, perchlorate, and hexavalent chromium. While 1,4-dioxane is not identified as a COC at any contaminated sites listed in the SWRCB's GeoTracker database, widespread detections in groundwater in the Study Area indicate that 1,4-dioxane is likely associated with contaminated sites. **Figure K-22** shows active and inactive leaking underground storage tank (LUST) sites. The primary COCs associated with LUST sites are petroleum hydrocarbons and gasoline additives including benzene, toluene, ethylbenzene, xylenes, and methyl tertiary butyl ether (MTBE).

In an effort to minimize or eliminate threats to groundwater supplies, WRD established the Groundwater Contamination Prevention Program. As part of this program, WRD created and administers the CBWCB Groundwater Contamination Forum, a data-sharing and discussion forum with key stakeholders that include the USEPA, DTSC, LARWQCB, CDPH (now the SWRCB Division of Drinking Water), USGS, and various cities and drinking water purveyors. In 2005, these stakeholders drafted and signed a Memorandum of Understanding, agreeing to meet regularly and share data on groundwater contaminated sites within the CBWCB. As a key stakeholder, WRD has been tracking and working in close consultation with the regulatory agencies to provide data and technical support to expedite investigations and cleanups at priority groundwater contaminated sites within the CBWCB.

Priority environmental release sites in the CBWCB were selected by WRD, with input from the other members of the CBWCB Groundwater Contamination Forum, based on certain criteria such as hydrogeology, depth and concentration of the contaminants, fate and transport of the COCs, distance to nearby water supply wells, presence of contaminated drinking water wells in the site vicinity, proximity to recharge areas, and status of site characterization/remediation. The current list of WRD's priority groundwater contaminated sites are provided in Appendix G *Hydrogeologic Conceptual Model and Existing Salt and Nutrient Groundwater Quality* of the SNMP**.**

Recent reports and data collected for environmental release sites can be downloaded from the following publicly-accessible websites:

- Revised 1/27/2015

3.6.7 Regional Groundwater Level Monitoring

Groundwater levels in the CBWCB have been monitored and recorded since the early 1900s. WRD tracks groundwater levels continuously in their nested monitoring wells located throughout the CBWCB using automatic data-loggers and by manually measuring the depth to water in the wells quarterly. Water levels in production wells located throughout the CBWCB are also tracked by WRD.

On November 4, 2009, the State Legislature amended the Water Code with SBx7-6, which mandated a statewide groundwater elevation monitoring program to track seasonal and long-term trends in groundwater elevations in California's groundwater basins. In accordance with this amendment to the Water Code, DWR developed the California Statewide Groundwater Elevation Monitoring (CASGEM) program. In October 2011, WRD was assigned to be the Designated Monitoring Entity (DME) responsible for collecting and reporting CBWCB groundwater level data to CASGEM. DWR developed an online system for DMEs to submit groundwater elevation data, which is compatible with DWR's Water Data Library. Water level data collected by DWR is available to the public at the following website: http://www.water.ca.gov/waterdatalibrary/.

In order to capture the daily and seasonal variations in water levels, WRD installed automatic data-logging equipment in most of the nested monitoring wells to measure and record water levels four times per day. In addition, water levels are manually measured at least quarterly in all the nested monitoring wells. WRD also obtains water level data from cooperating entities such as the pumpers, DWR, and LACDPW, who collect water levels from their wells. These data are entered into WRD's Geographic Information System (GIS) water level database for archiving and analysis.

Water level measurements recorded during the water year, groundwater elevation contour maps based on Fall measurements, and groundwater level change maps based on the difference between that Fall and the previous Fall measurements are presented and discussed in each RGWMR (see Section 3.6.1). Long-term water level hydrographs and historical annual change in groundwater storage are presented in WRD's annual *Engineering Survey and Report*. These reports are available for download on the WRD website: http://www.wrd.org/engineering/groundwater-engineering-reports.php.

The LACDPW also monitors water levels in a network of wells in the Study Area and these data can be accessed on their website (http://dpw.lacounty.gov/general/wells/).

3.7 Climatological Monitoring

Precipitation has been continuously recorded in the region since the beginning of the twentieth century. LACDPW operates 244 rain gauges and 15 evapotranspiration stations in Los Angeles County. Maps and index lists of the stations are provided in **Attachment K-O**. Rainfall and evaporation data are published by the LACDPW in their annual Hydrologic Reports (http://dpw.lacounty.gov/wrd/report/).

Data relating to precipitation in the region is also available from the California Irrigation Management Information System (CIMIS). CIMIS, a division of the California Department of

Water Resources (DWR), tracks and records climate data in the State. In addition to precipitation, these weather stations collect data for sunlight, wind speed, humidity, and calculate evaporation rates. A map and information on the two stations located in the Study Area are provided in Attachment K-O. Data can be downloaded from the CIMIS website (http://wwwcimis.water.ca.gov/cimis/welcome.jsp).

Precipitation water quality data are available from the Clean Air Status and Trends Network (CASTNET) on the USEPA website (http://epa.gov/castnet/javaweb/index.html). CASTNET is a national air quality monitoring network designed to provide data to assess trends in air quality, atmospheric deposition, and ecological effects due to changes in air pollutant emissions. Precipitation water quality was collected from the CASNET Converse Station for estimation of the S/N loading associated with precipitation infiltration and dry deposition. A map showing the location of the Converse station is provided in Attachment K-O. Generally, precipitation has very low S/N concentrations. Dry deposition or atmospheric deposition is the process by which airborne pollutants are deposited to the earth. These pollutants include, but are not limited to, sulfur dioxide, nitrogen oxides, ammonia, and mercury and represent a source of S/N loading to groundwater.

4 Constituents of Emerging Concern (CECs)

CECs are a diverse group of relatively unregulated chemicals that have been shown to occur at trace levels in municipal wastewater discharges, ambient receiving waters, and drinking water supplies. CECs include pharmaceuticals, personal care products, and other commercial and industrial compounds. These chemicals are now detected as the result of more sensitive analytical methods. Information regarding their public health significance is evolving with the development of acceptable daily intake levels and drinking water equivalent levels.

In the Study Area, monitoring for CECs is being conducted for the groundwater recharge projects that utilize recycled water and for special studies as summarized in **Table K-27**. There are also ongoing leading edge research projects sponsored by entities such as the Water Research Foundation and the WateReuse Research Foundation and some of the SNMP stakeholders. Given the robustness of data for CECs, including the reliability of analytical methods, there is a sufficient level of CEC monitoring being performed in the Study Area, including annual monitoring at several groundwater recharge sites. This monitoring is supplemented by ongoing leading edge research efforts.

4.1 California Regulatory Requirements for CECs

In accordance with the SWRCB Recycled Water Policy, a Science Advisory Panel (Panel) was formed to identify a list of CECs for monitoring recycled water used for groundwater recharge and landscape irrigation. The Panel completed its report (Panel Report) on CECs in June 2010 (http://ftp.sccwrp.org/pub/download/DOCUMENTS/CECpanel/CECMonitoringInCARecycledWater_FinalReport.pdf) and recommended monitoring of selected health-based and treatment performance indicator CECs and surrogates for groundwater recharge projects. No CEC monitoring was recommended for landscape irrigation due to the low risk for ingestion of the water. The groundwater recharge monitoring recommendations were directed at surface spreading using tertiary treated recycled water (specifically for recycled water and groundwater monitoring) and injection projects using reverse osmosis and advanced oxidation (specifically for recycled water monitoring). The Panel did not address or make recommendations related to CEC monitoring for SNMPs.

The Recycled Water Policy was amended by the SWRCB on January 22, 2013 (http://www.swrcb.ca.gov/water_issues/programs/water_recycling_policy/draft_amendment_to_policy.shtml) and was approved by the Office of Administrative Law on April 25, 2013 (SWRCB, 2013). The Recycled Water Policy Amendment (http://www.swrcb.ca.gov/board_decisions/adopted_orders/resolutions/2013/rs2013_0003_a.pdf) provides the final list of specific CECs for monitoring (summarized in **Table K-28**) and monitoring frequencies to be incorporated into permits for planned groundwater recharge projects. The next update by an expert panel is scheduled to occur in 2015.

Regulations regarding groundwater replenishment (both surface and subsurface applications) using recycled municipal wastewater are specified in California Code of Regulations, Title 22, Division 4, Chapter 3, Articles 5.1 and 5.2. These regulations include a number of measures to ensure protection of groundwater quality, including CEC monitoring.

Table K-27 Summary of CEC Monitoring / Studies for the CBWCB

Project	**Media Monitored**	**Monitoring Locations**	**Constituents of Emerging Concern (CECs) Monitored**	**Frequency**	**Responsible Agency and Reporting/Database**
MONITORING PROGRAM					
Alamitos Gap Seawater Intrusion Barrier	Advanced treated recycled water	Plant product water from WRD's Leo J. Vander Lans Advanced Water Treatment Facility (Vander Lans AWTF)	• 17β estradiol • Caffeine • Triclosan • DEET • Sucralose • NDMA	Annually, with the exception of NDMA, which is monitored quarterly *CEC monitoring is conducted in accordance with the Recycled Water Policy and State regulations for groundwater replenishment using recycled water (California Code of Regulations (CCR), Title 22, Division 4, Chapter 3, Water Recycling Criteria)*	Water Replenishment District of Southern California (WRD) Quarterly and annual reports submitted to the Los Angeles Regional Water Quality Control Board (LARWQCB) and the State Water Resources Control Board (SWRCB) Division of Drinking Water (formerly California Department of Public Health [CDPH]) and posted on the SWRCB GeoTracker online database: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100006793

Project	Media Monitored	Monitoring Locations	Constituents of Emerging Concern (CECs) Monitored	Frequency	Responsible Agency and Reporting/Database
MONITORING PROGRAM					
Dominguez Gap Seawater Intrusion Barrier	Advanced treated recycled water	Plant product water from City of Los Angeles' Terminal Island Water Reclamation Plant/Advanced Waste Treatment Facilities	• EDCs • Pharmaceuticals and other Chemicals	Annually *In future permit amendments, modifications to CEC monitoring will be made in accordance with the Recycled Water Policy and State regulations for groundwater replenishment using recycled water (CCR, Title 22, Division 4, Chapter 3, Water Recycling Criteria)*	City of Los Angeles Quarterly and annual reports submitted to LARWQCB and the SWRCB Division of Drinking Water (formerly CDPH) and posted on the SWRCB GeoTracker online database: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100000534

Project	Media Monitored	Monitoring Locations	Constituents of Emerging Concern (CECs) Monitored	Frequency	Responsible Agency and Reporting/Database
MONITORING PROGRAM					
West Coast Basin Seawater Intrusion Barrier	Advanced treated recycled water	Plant product water from WBMWD's Edward C. Little Water Recycling Facility (ELWRF)	• EDCs • Pharmaceuticals and other Chemicals	Annually *In future permit amendments, modifications to CEC monitoring will be made in accordance with the Recycled Water Policy and State regulations for groundwater replenishment using recycled water (CCR, Title 22, Division 4, Chapter 3, Water Recycling Criteria)*	West Basin Municipal Water District (WBMWD) Quarterly and annual reports submitted to LARWQCB and the SWRCB Division of Drinking Water (formerly CDPH) and posted on the SWRCB GeoTracker online database: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100000047

Project	Media Monitored	Monitoring Locations	Constituents of Emerging Concern (CECs) Monitored	Frequency	Responsible Agency and Reporting/Database
MONITORING PROGRAM					
SDLAC's National Pollutant Discharge Elimination System Permits	Tertiary-treated recycled water	Effluent from SDLAC's: • Pomona Water Reclamation Plant (WRP) • Whittier Narrows WRP • San Jose Creek WRP (expected monitoring in the future) • Los Coyotes WRP (expected monitoring in the future) • Long Beach WRP (expected monitoring in the future)	• Endocrine Disrupting Chemicals (EDCs) • Pharmaceuticals and Personal Care Products (PPCPs) • Pesticides • Other CECs	Annually for 2 years	Sanitation Districts of Los Angeles County (SDLAC) Annual reports submitted to LARWQCB and posted on the SWRCB California Integrated Water Quality System (CIWQS) online database: http://ciwqs.waterboards.ca.gov/ciwqs/readOnly/PublicReportEsmrAtGlanceServlet?inCommand=reset

Project	Media Monitored	Monitoring Locations	Constituents of Emerging Concern (CECs) Monitored	Frequency	Responsible Agency and Reporting/Database
MONITORING PROGRAM					
Groundwater Ambient Monitoring and Assessment Program (GAMA)	Groundwater	Public supply wells located throughout the State, including those located within the CBWCB	• Pharmaceuticals • Potential wastewater indicator compounds	Once every 10 years	United States Geological Survey (USGS) and SWRCB Goldwrath et al., 2012 Report available from: http://www.swrcb.ca.gov/water_issues/programs/gama/docs/dsr_coastallabasin.pdf
SPECIAL STUDIES/RESEARCH PROJECTS					
1,4-Dioxane and 1,2,3-Trichloropropane (1,2,3-TCP) Occurrence Studies	Groundwater	WRD's nested groundwater monitoring wells, which are screened in specific aquifers	• 1,4-Dioxane • 1,2,3-TCP	1,4-Dioxane sampling conducted in nested wells located in the Montebello Forebay from 2002 through 2003 1,4-Dioxane and 1,2,3-TCP sampling conducted in all nested wells in 2012	WRD WRD's annual Regional Groundwater Monitoring Reports: http://www.wrd.org/engineering/groundwater-engineering-reports.php WRD's online GIS database: http://gis.wrd.org/wrdmap/login.asp

Project	Media Monitored	Monitoring Locations	Constituents of Emerging Concern (CECs) Monitored	Frequency	Responsible Agency and Reporting/Database
SPECIAL STUDIES/RESEARCH PROJECTS					
Expert Panel Advanced Treated Recycled Water Study	Advanced treated recycled water	Effluent from WBMWD's Edward C. Little Water Recycling Facility	• EDCs • PPCPs	Quarterly for one year beginning in August 2009; frequency lowered to once per year and monitoring is conducted as part of routine permit compliance program	WBMWD Quarterly and annual reports submitted to LARWQCB and the SWRCB Division of Drinking Water (formerly CDPH) and posted on the SWRCB GeoTracker online database: http://geotracker.waterboards.ca.gov/profile_report.asp?global_id=WDR100000047
Development Of Indicators and Surrogates for Chemical Contaminant Removal during Wastewater Treatment and Reclamation	• Tertiary recycled water • Groundwater	In Central Basin: • Spreading basin • Monitoring wells • Soil columns	• EDCs • PPCPs	N/A	WateReuse Research Foundation (WRF) Project No. 03-014 WRF Report No. 03-014-01 (Drewes et al., 2008): http://www.waterboards.ca.gov/water_issues/programs/grants_loans/water_recycling/research/03_014_01.pdf

Project	Media Monitored	Monitoring Locations	Constituents of Emerging Concern (CECs) Monitored	Frequency	Responsible Agency and Reporting/Database
SPECIAL STUDIES/RESEARCH PROJECTS					
Toxicological Relevance of Endocrine Disruptors and Pharmaceuticals in Drinking Water	Influent and effluent samples of water treatment plants	20 Drinking water treatment plants and 4 wastewater treatment plants across the continental U.S., including 195 plants located in States within the Pacific Time Zone	Developed acceptable daily intake (ADI) values and drinking water equivalent levels (DWEL) for: • Pharmaceuticals • EDCs • Steroid hormones • Phytoestrogens	N/A	Water Research Foundation Project No. 3085 and WRRF Project No. 04-003 Report (Snyder et al., 2008) available from WRRF: https://www.watereuse.org/files/images/2008-AwwaRF-3085.pdf
NDMA Fate and Transport Study	• Groundwater • Surface water • Tertiary treated recycled water	• Wells in the vicinity of the Montebello Forebay Spreading Grounds • Surface water in the vicinity of SDLAC's Pomona, Whittier Narrows, and San Jose Creek WRPs • Effluent (tertiary treated recycled water) from SDLAC's Pomona, Whittier Narrows, and San Jose Creek WRPs	NDMA (Also conducted modeling for key receptor wells, surface water, and groundwater)	N/A	SDLAC Montebello Forebay Attenuation and Dilution Studies Report (Kennedy/Jenks/Todd, 2008) available at: http://www.waterboards.ca.gov/waterrights/water_issues/programs/bay_delta/docs/cmnt081712/srcsd/kennedystudies.pdf

Project	Media Monitored	Monitoring Locations	Constituents of Emerging Concern (CECs) Monitored	Frequency	Responsible Agency and Reporting/Database
SPECIAL STUDIES/RESEARCH PROJECTS					
Contributions of Household Chemicals to Sewage and their Relevance to Municipal Wastewater Systems and the Environment	• Raw sewage • Secondary effluent from wastewater reclamation plant • Tertiary recycled water	Water reclamation plant (facility unnamed in the report) in the Central Basin including a pilot scale membrane bioreactor	• EDCs • PPCPs	N/A	WRRF Project No. 04-018 and Water Environment Research Foundation Report (Drewes et al., 2009) available from WRRF: http://www.watereuse.org/files/images/03-CTS-21UR.pdf
Monitoring Strategies for CECs in Recycled Water	Existing recycled water data	Survey sent to California stakeholders	• PPCPs • EDCs	N/A	Southern California Coastal Water Research Project (SCCWRP) and SWRCB Report (Anderson et al., 2010) available at: http://ftp.sccwrp.org/pub/download/DOCUMENTS/CECpanel/CECMonitoringInCARecycledWater_FinalReport.pdf

Project	Media Monitored	Monitoring Locations	Constituents of Emerging Concern (CECs) Monitored	Frequency	Responsible Agency and Reporting/Database
SPECIAL STUDIES/RESEARCH PROJECTS					
Development and Application of Tools to Assess and Understand the Relative Risks of Drugs and Other Chemicals in Indirect Potable Reuse	Existing monitoring data associated with the Montebello Forebay Groundwater Recharge Project	N/A	Developed tolerable daily intake (TDI) values and DWELs values for: • PPCPs • EDCs	N/A	WRRF Project No. 06-018 Report (Bruce et al., 2010) available from WRRF: http://www.watereuse.org/product/06-018
Sampling Report for Emerging Constituents in the Santa Ana Region	• Treated wastewater • Surface water • Untreated imported water	• Effluent of 22 wastewater treatment plants in the Santa Ana River Watershed • 2 locations along the Santa Ana River) • 1 location from the State Water Project • 1 location near the terminus of the Colorado River Aqueduct	• Pharmaceuticals • Food additives • Pesticides	Samples collected in 2010, 2011, and 2012	Santa Ana Watershed Project Authority (SAWPA) Report (SAWPA, 2012) available from: http://www.sawpa.org/wp-content/uploads/2012/05/EC-Report-for-2012-Final.pdf

Project	Media Monitored	Monitoring Locations	Constituents of Emerging Concern (CECs) Monitored	Frequency	Responsible Agency and Reporting/Database
SPECIAL STUDIES/RESEARCH PROJECTS					
1,4-Dioxane Occurrence and Fate Study	• Raw wastewater • Tertiary-treated recycled water	Influent and effluent of SDLAC's Pomona, Whittier Narrows, and San Jose Creek WRPs	1,4-Dioxane	Study conducted in 2011	SDLAC Data available upon request from SDLAC
Development of Surrogates to Determine the Efficacy of Soil Aquifer Treatment Systems for the Removal of Organic Chemicals	• Tertiary-treated recycled water • Groundwater	Montebello Forebay Spreading Grounds: • Spreading basins • Monitoring Wells in the proximity to the spreading basins	• EDCs • PPCPs	N/A	WRRF Project No. 05-004 Report (Drewes and Snyder, 2011) available from WRRF: http://www.watereuse.org/product/05-004-1
Monitoring Strategies for CECs in California's Aquatic Ecosystems	Existing data for: • Recycled water • Surface water • Stormwater	Review of literature, CEC recycled water data, and available data from the 2011 Los Angeles Regional Water Quality Control Board Surface Water CEC Study	• EDCs • PPCPs • Pesticides	N/A	Southern California Coastal Water Research Project (SCCWRP) Report (Anderson et al., 2012) available from SCCWRP: http://ftp.sccwrp.org/pub/download/DOCUMENTS/TechnicalReports/692_CECEcosystemsPanelReport_Final.pdf

Project	Media Monitored	Monitoring Locations	Constituents of Emerging Concern (CECs) Monitored	Frequency	Responsible Agency and Reporting/Database
SPECIAL STUDIES/RESEARCH PROJECTS					
Role of Retention Time in the Environmental Buffer of Indirect Potable Reuse Projects	• Tertiary-treated recycled water • Groundwater	Montebello Forebay Spreading Grounds: • Spreading basins • Monitoring Wells in the proximity to the spreading basins	• EDCs • PPCPs	N/A	WRRF Project No. 10-005 This study is In progress; a report is expected to be issued by WRRF in 2014/15
Occurrence and Fate of Chemicals of Emerging Concern in Coastal Urban Rivers Receiving Treated Municipal Wastewater	• Tertiary-treated recycled water • Surface water	• San Gabriel River • Los Angeles River	• EDCs • PPCPs • Pesticides • Other CECs	Study conducted in 2011	SCCWRP http://www.sccwrp.org Study is in progress; report will be issued by SCCWRP when available
CECs in Coastal Watersheds in the Los Angeles Region and in Sediment & Fish Tissue (Phase II)	• Surface water • Sediment • Fish Tissue	• Santa Clara River • San Gabriel River • Los Angeles River	• EDCs • PPCPs • Pesticides • Other CECs	Sampling expected to be conducted in 2013	SCCWRP http://www.sccwrp.org Study is in progress; report is expected to be issued by SCCWRP in 2014

Table K-28 SWRCB Recycled Water Policy CECs to be Monitored

Constituent[a]	Constituent Group	Relevance/Indicator Type	Reporting Limit (µg/L)
Groundwater Recharge and Reuse – Surface Application			
17β-estradiol	Steroid hormones	Health	0.001
Caffeine	Stimulant	Health & Performance	0.05
N-Nitrosodimethylamine (NDMA)	Disinfection byproduct	Health	0.002
Triclosan	Antimicrobial	Health	0.05
Gemfibrozil	Pharmaceutical	Performance	0.01
Iopromide	Pharmaceutical	Performance	0.05
N,N-Diethyl-meta-toluamide (DEET)	Personal care product	Performance	0.05
Sucralose	Food additive	Performance	0.1
Groundwater Recharge and Reuse – Subsurface Application			
17β-estradiol	Steroid hormones	Health	0.001
Caffeine	Stimulant	Health & Performance	0.05
NDMA	Disinfection byproduct	Health & Performance	0.002
Triclosan	Antimicrobial	Health	0.05
DEET	Personal care product	Performance	0.05
Sucralose	Food additive	Performance	0.1

µg/L – micrograms per liter

a. Monitoring frequency is quarterly for the initial assessment phase, semi-annually for the baseline phase, and semi-annually to annually for the standard operation phase; CECs can be removed or monitoring can increase based on the results

Regulations regarding groundwater replenishment (both surface and subsurface applications) using recycled water are specified in California Code of Regulations, Title 22, Division 4, Chapter 3, Articles 5.1 and 5.2. These regulations establish monitoring requirements for indicator compounds that will be selected by the project sponsor based on several factors, including the indicator compound's ability to characterize the presence of CECs. Project sponsors must conduct studies at initial operation of the groundwater recharge project and at 5-year intervals thereafter to determine the occurrence of indicator compounds in the recycled water. The protocol for the occurrence study, the study's results, and the indicator compounds to be monitored shall be reviewed and approved by the SWRCB Division of Drinking Water (formerly CDPH).

The LARWQCB has taken actions to begin to address CECs and has begun to include requirements for CEC Special Studies in NPDES permits for Publicly Owned Treatment Works in the region. The development of a CEC monitoring strategy for the Los Angeles region was identified as a priority project during the project selection phase of the 2011-13 Basin Plan triennial review.

In January 2013, the LARWQCB sent letters to NPDES dischargers in the Los Angeles Region discharging to fresh surface water with requirements to conduct CEC special studies, including SDLAC's Pomona and Whittier Narrows WRPs, which amended existing CEC requirements. Effective immediately, the CECs required to be analyzed in NPDES-permit required special studies are to be replaced by the CECs in **Table K-29** and monitored annually for at least two years, with results to be included in annual reports. Unless required by another condition of the permit, data collection is not required for constituents for which at least two years of data have already been collected.

Table K-29 January 2013 Los Angeles Regional Water Quality Control Board NPDES Special Study CEC Effluent Monitoring

Constituents – Monitoring 1/year for 2 Years	
17-Alpha Ethinylestradiol	Lipitor
17-Beta Estradiol	Iopromide
Estrone	Sulfamethoxazole
Bisphenol A	Trimethoprim
Nonylphenol	Salicylic acid
Nonylphenol Polyethoxylates	Tris (2-chloroethyl) phosphate (TCEP)
Octylphenol	Tris (1-chloro-2-propyl) phosphate (TCPP)
Octylphenol Polyethoxylates	Tris (2-chloroethyl) phosphate (TDCP)
Polybrominated Diphneyl Ethers	Triclosan
Acetaminophen	Bifenthrin
Amoxicillin	Permethrin
Azithromycin	Chlorpyrifos
Carbamazepine	Galaxolide
Caffeine	Diclofenac
Ciproflaxin	Butyl benzyl phthalate
N,N-Diethyl-m-toluamide (DEET)	Perfluorooctane Sulfonate (PFOS)
Dilantin	Fipronil
Gemfibrozil	Meprobamate
Ibuprofen	

CEC monitoring requirements have been included in existing permits issued for the injection of AWT recycled water at the AGB, DGB, and WCBB (see Section 3.1), as summarized in Table K-27. The list of CECs is based on former (pre-2008) draft groundwater recharge regulations that had been issued by the California Department of Public Health (designated as the Endnote 5 compounds) and consists of the following:

- Hormones: ethinyl estradiol, 17-B estradiol, estrone.
- "Industrial" endocrine disruptors: bisphenol A, nonylphenol and nonylphenol polyethoxylate, octylphenol and octylphenol polyethoxylate, polybrominated diphenyl ethers.

- Pharmaceuticals and others substances: acetaminophen, amoxicillin, azithromycin, caffeine, carbamazepine, ciprofloxacin, ethylenediamine tetra-acetic acid, gemfibrozil, ibuprofen, iodinated contrast media, lipitor, methadone, morphine, salicylic acid, and triclosan.

As discussed in Section 3.6.5 of this Plan, the USGS (2009) has conducted some groundwater monitoring for CECs in the CBWCB under the GAMA Program.

In addition, the Southern California Coastal Water Research Project (SCCWRP, 2012) with the David and Lucile Packard Foundation sponsored an expert panel that prepared a report (Monitoring Strategies for Chemicals of Emerging Concern (CECs) in California's Aquatic Ecosystems: Recommendations of a Science Advisory Panel, http://ftp.sccwrp.org/pub/download/DOCUMENTS/TechnicalReports/692_CECEcosystemsPanelReport_Final.pdf) that provides the State with recommendations on appropriate monitoring and management strategies for CECs to limit the impact on oceans, estuaries and coastal wetlands, and freshwater ecosystems. The recommendations were presented to the SWRCB in October 2012. Based on these recommendations and input from stakeholders, the SWRCB is preparing a staff report that will be presented to their Board to seek input and direction on CEC monitoring for NPDES permits, including discharges to inland surface waters.

4.2 CEC Special Studies

Stakeholders in the Study Area have conducted or are currently affiliated with a number of studies that are investigating CECs. Examples include:

- In September 2007, SDLAC began analyzing for CECs in the effluent of their wastewater treatment plants, including the Long Beach WRP, Los Coyotes WRP, Pomona WRP, Whittier Narrows WRP, and San Jose Creek WRP. SDLAC prepared a report (provided as **Attachment K-P**) that discusses the program for WRP effluent samples collected from September 2007 to July 2012. SDLAC's report also includes results for N-nitrosodimethylamine (NDMA), butyl benzyl phthalate, bis(2-ethylhexyl)phthalate, and chlorpyrifos. Although these constituents are not typically classified as CECs, they were treated as CECs by the Recycled Water Policy Science Advisory Panel's investigation of CECs and thus included in this evaluation. The list of CECs and number of data points for each constituent for WRPs in the Study Area is presented in **Table K-30**. Other than NDMA, none of the detected CECs exceeded monitoring triggers for human-health related effects established by the SWRCB Recycled Water Policy Panel.

Table K-30 Number of Data Points – SDLAC WRP Effluent CEC Monitoring

Constituent	SDLAC WRPs[a] – Number of Data Points					
	LB	LC	POM	SJCE	SJCW	WN

a. Sanitation District of Los Angeles County's (SDLAC's) Water Reclamation Plants (WRPs): Long Beach (LB); Los Coyotes (LC); Pomona (POM); San Jose Creek East (SJCE); San Jose Creek West (SJCW); and Whittier Narrows (WN)

b. N,N-Diethyl-meta-toluamide (DEET), Polybrominated diphenyl ethers (PBDE), Tris (2-chloroethyl) phosphate (TCEP)

- SDLAC study of NDMA fate and transport at the Montebello Forebay (Kennedy/Jenks/Todd, 2008). The study was designed to assess the transport and fate of NDMA between groundwater and SDLAC's Pomona WRP, San Jose Creek WRP, and Whittier Narrows WRP. NDMA is both formed and degraded in the wastewater treatment process, and levels in the effluent can vary substantially with different treatment processes. The study found that NDMA is attenuated in both surface water systems due to UV from exposure to sunlight and groundwater systems due to biodegradation through soil aquifer treatment. The study concluded that NDMA in recycled water recharged at the MFSG does not impact nearby water supply wells.
- In May, June, and July 2011, the SDLAC monitored effluent samples at the San Jose Creek WRP, Pomona WRP, and Whittier Narrows WRP as part of a three-month study to investigate the occurrence of 1,4-dioxane in the influent and its fate through the WRP treatment processes. There appears to be a consistent low level of 1,4-dioxane in all WRP effluent.
- Between 2002 and 2003, WRD conducted a groundwater investigation in the Montebello Forebay and results showed that 1,4-dioxane was not detected in any of its routinely monitored nested groundwater monitoring wells.

- In 2012, WRD analyzed samples from all their nested groundwater monitoring wells for 1,4-dioxane and 1,2,3-TCP. In the Central Basin, 1,4-dioxane was detected in 12 out of 30 nested monitoring well locations between 1 and 10 µg/L; most detections are in and around the Montebello Forebay. 1,2,3-TCP was detected in shallow zones at two nested monitoring locations in the Central Basin. In the West Coast Basin, 1,4-dioxane was detected at one nested monitoring location in the shallowest zone and no 1,2,3-TCP was detected.
- Drinking water systems are not required by State regulations to monitor for 1,4-dioxane. Nevertheless, because of concerns about possible contamination, a number of systems were directed by CDPH (now the SWRCB Division of Drinking Water) or voluntarily sampled their supplies for 1,4-dioxane. Based on samples collected between 2000 and 2011, 1,4-dioxane was detected in some drinking water wells located within the CBWCB. A summary of the 1,4-dioxane data is reported on the following website: http://www.cdph.ca.gov/certlic/drinkingwater/Pages/1,4-Dioxane.aspx.
- In August 2009, WBMWD commenced a CEC study of its AWT recycled water based on recommendations from an expert panel that was convened by WBMWD to support increasing the percentage of recycled water injected at the WCBB to 100 percent. The study consists of quarterly monitoring for one year for atrazine, boron, carbamazepine, DEET, 1,4-dioxane, estrone, gemfibrozil, iopromide, meprobamate, dilantin, sulfamethoxazone, and TECP. The data were provided to CDPH (now the SWRCB Division of Drinking Water) and the LARWQCB. The monitoring frequency was subsequently lowered to once per year and included in LARWQCB reports.
- During 2010 through 2011, samples were collected from 23 different wastewater treatment plants operating in the Santa Ana region, from two locations along the Santa Ana River (MWD crossing and Prado Dam), one location in the State Water Project (Devil Canyon), and one location near the terminus of the Colorado River Aqueduct (San Jacinto West Portal) (Risk Sciences, 2011). The State Project Water and Colorado River water samples were representative of imported water used in the SNMP Study Area. Samples were analyzed for 11 analytes in 2010, 13 analytes in 2011, and 15 analytes in 2012 including pharmaceuticals, food additives, and pesticides. The report is available at: http://www.sawpa.org/wp-content/uploads/2012/05/EC-Report-for-2012-Final.pdf.
- There have been multiple WateReuse Research Foundation (WRRF), Water Environment Research Foundation, and Water Research Foundation studies related to CEC indicators and surrogates, treatment, analytical methods, and health effects. Many are specific to the existing groundwater recharge projects in the Study Area including the following studies.
    - WateReuse Research Foundation (WRF) Project No. 03-014 – Drewes et al. (2008) evaluated CEC surrogates and indicators for an unnamed facility in Central Basin to evaluate soil aquifer treatment performance looking at tertiary recycled water and groundwater. CEC were grouped into removal categories (good > 90 percent), intermediate (25 to 90 percent), and poor (< 25 percent). Only two CEC were in the poor removal category (carbamazepine and

primidone). The report is available at: http://www.waterboards.ca.gov/water_issues/programs/grants_loans/water_recycling/research/03_014_01.pdf.

- Water Research Foundation Project No. 3085 and WRRF Project No. 04-003 – Synder et al. (2008) addressed the fundamental issue of potential human health impacts from the trace concentrations of endocrine disrupting chemicals (EDCs) and pharmaceuticals and personal care products (PPCPs) detected in drinking waters from across the United States by combining toxicological literature reviews and analytical monitoring results. The study developed drinking water equivalent levels (DWELs) for 16 PPCPs and 13 EDCs and risk metrics that can be used to evaluate concentrations of CECs in recycled water and drinking water. The report is available at: https://www.watereuse.org/files/images/2008-AwwaRF-3085.pdf.
- WRRF Project No. 04-018 and Water Environment Research Foundation Study – Drewes et al. (2009) evaluated CECs for a water reclamation plant (unnamed in report) located in the Central Basin and looked at removal during biological treatment. For most of the compounds evaluated, secondary treatment achieved 80 percent removals of the CECs studied. The report is available at: http://www.watereuse.org/files/images/03-CTS-21UR.pdf.
- WRRF Project No. 06-018 – Bruce et al. (2010) continued the work of Snyder et al. (2008) by developing tolerable daily intake (TDI) values and DWELs for 43 CECs, including pharmaceuticals and EDCs. The study also developed risk metrics that can be used to evaluate concentrations of CECs in recycled water and drinking water. The report is available at: http://www.watereuse.org/product/06-018.
- WRRF Project No. 05-004 – Drewes and Snyder (2011) evaluated the removal of ECDs and PPCPs in the Montebello Forebay Spreading Grounds by evaluating tertiary recycled water in the spreading basins and the San Gabriel River Spreading Grounds test basin and observing concentrations in adjacent monitoring wells. Of the compounds studies, most were well removed with the exception of some CECs, including carbamazepine, primidone, DEET, and flame retardants. It is noteworthy, based on other research, to point out that the concentration of recalcitrant compounds found in the recycled water and groundwater are in nanograms per liter (ng/L) levels compared to corresponding DWELs that are at microgram per liter (ug/L) levels. The report is available at: http://www.watereuse.org/product/05-004-1.
- WRRF Project No. 10-005 – Jörg E. Drewes is the principal investigator for a project that is evaluating CEC removal at the San Gabriel River Spreading Grounds test basin and adjacent monitoring wells. The CECs include PPCPs and EDCs. The report for the research is expected to be issued in 2014/15.

5 Conclusion

In accordance with the Recycled Water Policy, this *Monitoring Plan* for the CBWCB SNMP was developed through a collaborative process involving major CBWCB stakeholders, including the WRD, LACDPW, WBMWD, LADWP, SDLAC, and MWD. For over 50 years, these agencies as well as other local agencies and numerous cities have been collaborating and implementing critical measures, such as water reclamation and reuse, water conservation, improved maintenance of supply and delivery infrastructure, and the capture and use of stormwater, to prevent overdraft and replenish the CBWCB aquifer system.

This SNMP Monitoring Program that was developed to assess TDS, chloride, and nitrate, which were determined in the SNMP to be the indicator compounds for S/Ns in the CBWCB. Seventy (70) WRD nested groundwater monitoring wells (referred to as the SNMP monitoring wells) at 13 locations throughout the CBWCB have been designated for S/N sampling and reporting as part of the SNMP Monitoring Program. WRD shall be responsible for collecting TDS, chloride, and nitrate data from the SNMP monitoring wells on a semi-annual basis and submitting this data to SWRCB's online GeoTracker database.

Other existing monitoring programs in the CBWCB, as well as special studies that have been conducted or are in progress were documented in this report. As documented, the existing monitoring programs provide a comprehensive and continuing assessment of the overall health of the basins and allow for proper management of S/N loading on a sustainable basis. The extensive amount of historical data collected in the CBWCB has allowed a regional characterization of S/N groundwater quality, development of water quality trends, and projection of future groundwater quality to be included in the SNMP, thereby demonstrating the adequacy of the existing monitoring programs. Thus, the CBWCB are highly managed and rigorously monitored groundwater basins and no additional monitoring programs were found to be warranted at this time.

Monitoring for CECs in the Study Area is being conducted for the groundwater recharge projects that utilize recycled water, wastewater treatment plants that discharge to surface water, and for special studies. There are also ongoing leading edge research efforts to further develop analytical methods and understand the health implications of low level detections. As such, no additional CEC monitoring was found to be warranted in the CBWCB and thus, not proposed as part of the SNMP Monitoring Program.

Based on results from the SNMP Monitoring Program, the SNMP *Monitoring Plan* will be updated as necessary. Additionally, the SNMP *Monitoring Plan* will be reviewed and updated as necessary as part of the SNMP review every 10 years.

Attachment K-A
List of Definitions

Below is a list of terms that provide an overall understanding of the Salt and Nutrient Management Plan (SNMP), including those used in this document.

Activated Sludge Biological Treatment – A treatment process that uses aeration tanks to bubble air through primary treated wastewater to supply air to microorganisms that feed on the organic materials in these tanks. The water is sent to settling tanks, where the microorganisms clump together and settle to the bottom, where they are removed and recycled back into the treatment process (also called Secondary Treatment).

Added salts and nutrients – Salt and nutrients that are added through the use of water sources, including fertilizers and amendments, leaching from dry deposition, and dissolution from formation media.

Advanced Oxidation – A chemical oxidation process that relies on the hydroxyl radical for the destruction of trace organic constituents found in water.

Advanced Water Treatment (AWT) – Wastewater treatment technologies used to remove total dissolved solids and or trace constituents for specific reuse applications.

Allowable Pumping Allocations – The Courts adjudicated maximum groundwater pumping rights for an individual or entity under the Central Basin Judgment and West Coast Basin Judgment.

Anti-Degradation – California's Anti-Degradation Policy requires that existing high quality water be maintained to the maximum extent possible. Lowering of the quality is allowed only if the change is consistent with maximum benefit to people of State, will not unreasonably affect present and potential beneficial uses, will not result in water quality lower than applicable standards. Waste discharge requirements for proposed discharges will result in the best practicable treatment or control of the discharge necessary to assure no pollution or nuisance and the highest water quality consistent with maximum benefit to people of the State.

Aquifer – A geologic formation under the ground that is saturated with groundwater and sufficiently permeable to allow movement of quantities of water to wells and springs.

Aquifer Storage and Recovery – The injection of water into an aquifer for later recovery and use.

Artificial Recharge – The process of adding a water source such as recycled water, stormwater, or imported water to aquifers under controlled conditions for withdrawal at a later date, or used as a barrier to prevent seawater or other contaminants from entering the aquifer. Water can be recharged by a number of methods including infiltration via basins or galleries or by the use of injection wells. See definition for Managed Aquifer Recharge.

Assimilative Capacity – The condition in which existing water quality is better than that required to support the most sensitive beneficial use(s) of the basin, i.e. existing salt and nutrient concentrations in groundwater are below Water Quality Objectives. See Current Assimilative Capacity and Future Assimilative Capacity.

Base Case (same as baseline and historical period) – The average source water and salt and nutrient inflows and outflows during the baseline/historical period (Water Year 2000-01 to 2009-10). The average of the Base Case is used for predicting the future 15-year water balances with adjustments in inflow and outflow based solely on future projects. See definition for Future Planning Period.

Baseline (same as Base Case and historical period) – The average source water and salt and nutrient inflows and outflows during the historical period (Water Year 2000-01 to 2009-10). The average of the Baseline is used for predicting the future 15-year water balances with adjustments in inflow and outflow based solely on future projects. See definition for Future Planning Period.

Basin Plan – Water Quality Control Plan that was issued by the Los Angeles Regional Water Quality Control Board (LARWQCB) in 1994 to preserve and enhance water quality and protect the beneficial uses of all regional waters in the Los Angeles Region. Specifically, the Basin Plan designates the beneficial uses for surface water and groundwater, establishes numerical objectives (referred to as Water Quality Objectives [WQOs]) that must be attained or maintained to protect the designated beneficial uses and conform to the State's Anti-Degradation Policy, and describes implementation programs to protect all waters in the region. The Basin Plan can be downloaded from this website: http://www.waterboards.ca.gov/losangeles/water_issues/programs/basin_plan/basin_plan_documentation.shtml.

Basin Plan Objective (BPO) – Numerical limits established for various constituents in groundwater. BPOs, also referred to as Water Quality Objectives (WQOs), are set forth in the Basin Plan that was issued by the LARWQCB. See definition for Basin Plan.

Best Management Practices (BMPs) – BMPs for stormwater address the increased volume and rate of runoff from impervious surfaces and the concentration of pollutants in the runoff. BMPs can include structural systems and non-structural programs.

Calibration – For the existing United States Geological Services (USGS) groundwater flow model of the Central Basin and West Coast Basin, calibration is the process of adjusting hydraulic properties to better simulate observed groundwater levels and trends. A calibration process was also conducted for the salt and nutrient loading analysis for the Salt and Nutrient Management Plan, whereby historical groundwater quality trends were compared with the mixing model predicted groundwater quality trends. Adjustments to loading assumptions were made to more closely match observed data.

California Environmental Quality Act – The State Water Resources Control Board (SWRCB) Recycled Water Policy requires that the Salt and Nutrient Management Plan (SNMP) comply with the applicable CEQA requirements. CEQA requires State and local agencies determine the potential significant environmental impacts of proposed projects and identify measures to avoid or mitigate these impacts where feasible. The CEQA Guidelines, which provide the protocol by which State and local agencies comply with CEQA requirements, are detailed in

California Code of Regulations, Title 14 § 15000 et seq. The basic purposes of CEQA are to: 1) inform decision makers and public about the potential significant environmental effects of a proposed project, 2) identify ways that environmental damage may be mitigated, 3) prevent significant, avoidable damage to the environment by requiring changes in projects, through the selection of alternative projects or the use of mitigation measures when feasible, and 4) disclose to the public why an agency approved a project if significant effects are involved (California Code Regulations, Title 14, § 15002(a)). CEQA analysis is a required part of the SNMP adoption process in accordance with the SWRCB's certified regulatory program. As such, for the purpose of RWQCB adoption of a Basin Plan amendment, the RWQCB will be the lead agency for purposes of CEQA and stakeholders will fund SNMP development including any necessary analysis and documentation to comply with CEQA.

Central Basin – The California Department of Water Resources (DWR) defines the Central Subbasin (DWR Subbasin Number 4-11.04) as occupying a substantial portion (277 square miles) of the Coastal Plain of the Los Angeles Groundwater Basin. In the SNMP, the Central "Subbasin" is referred to as the Central "Basin". The WRD boundaries include a portion, but not all of the DWR Central Basin extent.

Chemicals of Concern – Specific constituents identified at environmental release sites to be the focus of monitoring and potential remediation.

Chloride – A common inorganic salt that is naturally-occurring and is commonly expressed in terms of milligrams per liter (mg/L). High concentrations of chloride near the coast may indicate seawater influence. Elevated chloride concentrations above the Secondary Maximum Contaminant Level of 500 mg/L are undesirable for aesthetic reasons related to taste, odor, or appearance of the water and not for health reasons; however, elevated chloride concentrations in water can damage crops, affect plant growth, and damage municipal and industrial equipment. For the SNMP, chloride, total dissolved solids (TDS), and nitrate have been determined to be the most appropriate indicators of salts and nutrients in the Central Basin and West Coast Basin (CBWCB). See definition for Salt and Nutrients.

Coastal Areas – Groundwater basin areas seaward of the seawater intrusion barriers and near the coast that have very high concentrations of total dissolved solids (TDS) and chloride and a lack of significant production. These areas were both included and excluded from calculation of Central Basin and West Coast Basin salt and nutrient (S/N) water quality averages.

Confined Aquifer – These aquifers exist where the groundwater is bounded between layers of impermeable substances like clay or dense rock. When tapped by a well, water in confined aquifers is forced up, sometimes above the soil surface.

Confining Unit or Aquitard – A layer of sediments of low hydraulic conductivity located adjacent to an aquifer.

Conservative – Conservative with respect to a constituent means a constituent that does not significantly interact with subsurface media (vadose zone and saturated zone) and therefore, is not readily attenuated in the subsurface.

Constituents of Emerging Concern (CECs) – CECs are generally chemicals for which there are no established water quality standards or Notification Levels (see definition below). These chemicals may be present in waters at very low concentrations and are now detected as the result of more sensitive analytical methods. Information regarding their health significance is evolving with the development of acceptable daily intake levels and drinking water equivalent levels; however, information is lacking on the full spectrum of potential CECs and their health significance in mixtures. CECs include several types of chemicals such as (i) pesticides, (ii) pharmaceuticals and ingredients in personal care products, (iii) veterinary medicines, (iv) endocrine disruptors, and others. The State Water Resources Control Board (SWRCB) Recycled Water Policy states that Salt and Nutrient Management Plan shall include a *". . . provision for annual monitoring of Emerging Constituents of Emerging Concern (e.g. endocrine disrupters, personal care products or pharmaceuticals) (CECs) consistent with recommendations by CDPH and consistent with any actions by the State Water Board taken pursuant to paragraph 10(b) of this Policy." (SWRCB, 2009 and 2013)*

Contaminated Sites – See Environmental Release Sites.

Current Assimilative Capacity – The difference between Basin Plan Water Quality Objectives and average ambient groundwater quality in the individual basin or subarea.

Delivered Water – Blend of various waters that are delivered to the seawater intrusion barriers for injection or to the Montebello Forebay Spreading Grounds and San Gabriel River for groundwater recharge. At the seawater intrusion barriers, a blend/mix of recycled and treated imported water is used for injection and at the Montebello Forebay Spreading Grounds and San Gabriel River, a blend/mix of recycled, untreated imported, and local surface water is used for recharge.

Desalters – Treatment facilities that extract and treat high chloride and TDS groundwater from areas impacted by seawater intrusion.

Dry Deposition or Atmospheric Deposition – The process by which airborne pollutants are deposited to the earth. These pollutants include, but are not limited to, sulfur dioxide, nitrogen oxides, ammonia, and mercury and represent a source of salt and nutrient (S/N) loading to groundwater.

Environmental Release Sites – Commercial and industrial sites where activities (e.g., leaking aboveground and underground storage tanks, leaking sewer and oil pipelines, and illegal discharges) have contaminated groundwater with localized plumes of petroleum fuels, solvents, and other hazardous substances.

Existing Water Quality – Current quality of groundwater in the basin over the most recent 5-year averaging period of 2007 through 2012. See definition for water quality averaging period.

Fate and Transport – The movement and attenuation of constituents in the environment. Salt and nutrient fate and transport is based on groundwater flow directions and rates and on the characteristics of individual salts and nutrients and subsurface media.

First Flush – Stormwater sample collected immediately following the first significant rainfall event of the year.

Fiscal Year – The period from July 1 to June 30 of the following year.

Forebay – An area where large volumes of surface water recharge the regional aquifers.

Future Assimilative Capacity – The difference between the predicted future groundwater quality at the end of the future planning period and basin plan water quality objectives.

Future Planning Period – Period of time over which future loading will be assessed. Since the historical period covers water years 2000-01 through 2009-10, the future planning period encompasses water years 2010-11 through 2024-25. See definition for historical period. While water year 2010-11 has passed, it is not included in the historical period because reporting tends to lag data collection and some data collected during water year 2010-11 that is required to support the historical period analysis may not be available or published yet.

Gaining Reach – A gaining reach of a river or stream is where groundwater recharges surface water.

Goals and Objectives – Goals and objectives for this project are related to plans for recharge and use of recycled water, stormwater/surface water, and imported water.

Greater Los Angeles County (GLAC) Integrated Regional Water Management Plan (IRWMP) – A regional project with the goal of optimizing local water resources to reduce the region's reliance on imported water.

Groundwater – Water found in the spaces between soil particles and cracks in rocks underground (located in the saturation zone). Groundwater is a natural resource that is used for drinking, recreation, industry, and growing crops.

Groundwater Basins Master Plan (GBMP) – The Water Replenishment District of Southern California (WRD), in coordination with other basin stakeholders, has developed a Draft Groundwater Basins Master Plan (GBMP). The intent of this plan is to provide a single reference document for parties operating within and maintaining the Central Basin and West Coast Basin (CBWCB). This GBMP complements the efforts of the Water Independence Now (WIN) program by identifying projects and programs to enhance basin replenishment, increase the reliability of groundwater resources, improve and protect groundwater quality, and ensure that the groundwater supplies are suitable for beneficial uses.

Groundwater Reliability Improvement Program (GRIP) – The Water Replenishment District of Southern California (WRD), in coordination with the Sanitation Districts of Los Angeles County (SDLAC) is developing the GRIP recycled water project as a part of WRD's Water Independence Now (WIN) strategy. The overall goal of GRIP is to offset the current use of imported water with recycled water for groundwater replenishment in the Central Basin. Specifically, GRIP objectives include: 1) provide a sustainable and reliable source of recycled water for groundwater basin replenishment via the Montebello Forebay, 2) implement a cost-effective and environmentally sound project, 3) protect the groundwater quality of the basin, 4) comply with pertinent regulatory requirements employing an institutionally feasible approach, and 5) provide up to 21,000 acre-feet per year (AFY) of recycled water consistent with current and future needs within approximately 10 years. As a result of multiple studies over a number of years to evaluate of a wide spectrum of potential water supply reliability improvement projects, two different GRIP projects, as described below, were determined to be the best alternatives to completely replace imported water (up to 21,000 AFY) for recharge at the Montebello Forebay Spreading Grounds. Potential water quality impacts of both GRIP alternatives were simulated by the SNMP mixing model.

- GRIP Recycled Water Project A (GRIP A) – A combination of tertiary-treated (11,000 acre-feet per year [AFY]) and AWT (10,000 AFY) recycled water to replace imported water.
- GRIP Recycled Water Project B (GRIP B) – 100% tertiary-treated recycled water (21,000 AFY) to replace imported water.

Historical Period – The period of time for assessment of baseline or base case salt and nutrient inflows and outflows, which covers Water Years 2000-01 through 2009-10.

Historical Sources of Salt and Nutrients – Includes historical agriculture, livestock, septic systems, and other sources that have contributed to salt and nutrient loading in the Central Basin and West Coast Basin.

Implementation Measures – Strategies, projects, or programs that were developed by stakeholders in the Central Basin and West Coast Basin to control, reduce, or manage (mitigate) salt and nutrient loading to the groundwater basin on a sustainable basis.

Imported Water – Water that is imported to the Central Basin and West Coast Basin (CBWCB) from three major sources: the Sacramento-San Joaquin Delta (northern California), Colorado River, and Owens Valley/Mono Basin (eastern Sierra Nevada Mountains). Metropolitan Water District of Southern California (MWD) imports surface water from northern California (State Water Project) and the Colorado River (via the 242-mile Colorado River Aqueduct) to the CBWCB. The Los Angeles Department of Water and Power (LADWP) imports water from the Owens Valley/Mono Basin to the City of Los Angeles via the Los Angeles Aqueduct.

Inflow – A type of water or constituent (or water balance component) that is flowing into the groundwater basin or subarea within the basin. See definition for Water Budget/Balance.

In-Lieu Program – Program established by the Water Replenishment of Southern California to offset the pumping in the Central Basin and West Coast Basin to lower the annual overdraft and reduce artificial replenishment needs. It helps provide an alternate means of replenishing the groundwater supply by encouraging basin pumpers to purchase surplus imported water when available instead of pumping groundwater. This can help raise water levels in areas that are otherwise more difficult to address.

Irrigation and Precipitation Return Flows – The portion of precipitation and applied irrigation that percolates to groundwater.

Local Water – Local water includes stormwater and base surface water flow.

Low Impact Development (LID) – Design techniques that infiltrate, filter, store, evaporate, and detain surface water runoff close to its source. LID can include management measures such as maintenance practices, street sweeping, public education, and outreach programs. The main goals of LID are to increase groundwater recharge and improve stormwater quality.

Managed Aquifer Recharge – The process of adding a water source such as recycled water to aquifers under controlled conditions for withdrawal at a later date, or used as a barrier to prevent saltwater or other contaminants from entering the aquifer. Water can be recharged by a number of methods including infiltration via spreading basins or by the use of injection wells. (See definition of Artificial Recharge; also called Groundwater Recharge.)

Managed Safe Yield – The amount of groundwater that can be withdrawn from the Central Basin and West Coast Basin without long-term adverse effects assuming natural managed aquifer recharge.

Maximum Contaminant Levels (MCL) – The highest level of a contaminant that is allowed in drinking water and is protective of human health. Primary MCLs are established by the United States Environmental Protection Agency and the State Water Resources Control Board, Division of Drinking Water (formerly the California Department of Public Health) and reflect not only the chemicals' health risks but also factors such as their detectability and treatability, as well as the cost of treatment.

Microfiltration (MF) – A treatment system that passes liquid through semipermeable membranes to exclude particles ranging in size from 0.005-2.0 micrometer (µm).

Mixing Model – A spreadsheet model that was developed for the Salt and Nutrient Management Plan to estimate salt and nutrient concentrations in groundwater. Future salt and nutrients inflows and outflows are mixed (instantaneously) with baseline concentrations to estimate future water quality.

Natural Safe Yield – The amount of groundwater that can be withdrawn from the Central Basin and West Coast Basin without adverse effect, assuming natural groundwater replenishment.

Nitrification/Denitrification (NdN) – A biological treatment process used for nitrogen removal that converts ammonia to nitrate, and nitrate to nitrogen gas.

Nitrate (NO_3) – A colorless, odorless, and tasteless compound that is present in some groundwater and is commonly expressed in terms of milligrams per liter (mg/L). Nitrate is the primary form of nitrogen detected in groundwater. High levels of nitrate in groundwater are associated with agricultural activities, septic systems, confined animal facilities, landscape fertilization, and wastewater treatment facilities. In the Central Basin and West Coast Basin (CBWCB), natural nitrate levels in groundwater are generally very low (typically less than the Maximum Contaminant Level of 10 mg/L as nitrogen) and well below the Basin Plan Objective of 45 mg/L. For the CBWCB Salt and Nutrient Management Plan, nitrate chloride, and total dissolved solids (TDS) have been determined to be the most appropriate indicators of salts and nutrients in the CBWCB. See definition for salt and nutrients.

Notification Levels (NLs) – Health-based advisory levels established by the State Water Resources Control Board, Division of Drinking Water (formerly the California Department of Public Health) for chemicals in drinking water that lack Maximum Contaminant Levels. When chemicals are found at concentrations greater than their NLs, certain requirements and recommendations apply to drinking water purveyors.

Nutrient Plant Uptake – The process by which plants absorb nutrients from applied water and surrounding soil.

Outflow – A type of water or constituent (or water balance component) that is flowing out of the groundwater basin or subarea within the basin. See definition for water budget/balance.

Ozonation – A chemical oxidation treatment process that uses ozone to react with contaminants in water. It is also used for disinfection.

Public Health Goals (PHGs) – Levels of contaminants in drinking water that would not be expected to pose a significant health risk to individuals consuming an average of two liters a day of that water over a 70-year lifetime. PHGs are established by the Office of Environmental Health Hazard Assessment (OEHHA). They are based solely on health risk considerations and do not consider costs or technical feasibility. Public water systems do not have to meet public health goals. However, water systems with more than 10,000 service connections are legally required to prepare an exceedance report every three years if one or more chemical contaminants exceed PHG levels.

Primary Treatment – A treatment process that allows for heavier solids in raw sewage to settle to the bottom of a tank and for the lighter materials, like plastic and grease, which float to the top, to be skimmed and removed and recycled back into the treatment process.

Priority Sites – Environmental release sites in the Central Basin and West Coast Basin that were selected by the Water Replenishment District of Southern California (WRD), with input from regulatory agencies, based on certain criteria, such as hydrogeology, depth and concentration of the contaminants, fate and transport of the constituents of concern, distance to nearby water supply wells, presence of contaminated drinking water wells in the site vicinity, proximity to recharge areas, and status of site characterization/remediation. WRD has been tracking and working in close consultation with the regulatory agencies to provide data and technical support to expedite investigations and cleanups at priority groundwater contaminated sites within the CBWCB. See definition for environmental release sites.

Project Contact – E-mail where comments, suggested edits, and questions on the Technical Memorandums (TMs), other project materials, or SNMP process may be directed (WRD@saltnutrient.com).

Projected Future Inflows and Outflows – The projected salt and nutrient inflows and outflows will be based on the average of the past ten years (2000-01 through 2009-10) of flows with changes based on future projects planned to be implemented in the next 15 years (2010-11 through 2024-25).

Project Website – The website established to disseminate information related to the Central Basin and West Coast (CBWCB) SNMP and includes a calendar of events and meetings, meeting agendas and minutes, meeting presentations, project schedules, contact information, deliverables, data, graphics and other materials (www.WRD.saltnutrient.com).

Public Drinking Water System – A public drinking water system means a system for the provision of water for human consumption through pipes or other constructed conveyances that has 15 or more service connections or regularly serves at least 25 individuals daily at least 60 days out of the year. Private domestic wells are not regulated by the State Water Resources Control Board, Division of Drinking Water (formerly California Department of Public Health).

Quality Assurance/Quality Control (QA/QC) – Quality Assurance (QA) is a procedure or set of procedures intended to ensure that a product or service under development (before work is complete, as opposed to afterwards) meets specified requirements. Quality Control (QC) is a procedure or set of procedures intended to ensure that a manufactured product or performed service adheres to a defined set of quality criteria or meets the requirements of the client or customer. Due to the large size of the Central Basin and West Coast Basin and numerous managed recharge projects, a large amount of data collected from many agencies and entities is required to support the Salt and Nutrient Management development effort. Generally, the data will be accepted as correct and reliable; however, data will be evaluated for inconsistencies and outliers.

Recharge Area – An area where surface water can infiltrate downward to reach the water table and contribute to the groundwater supply. A recharge area can also refer to an injection well that pumps water down and into an aquifer thereby replenishing the aquifer.

Recycled Water – Domestic or municipal wastewater which has been treated to a quality suitable for a beneficial use.

Replenishment Operations – Managed aquifer recharge operations including spreading grounds and seawater intrusion barriers.

Reverse Osmosis (RO) – A treatment process where pressure greater than the osmotic pressure is applied to water to drive the more concentrated solution to the other side of the membrane and the membrane acts as a barrier to contaminants, such as salts. The permeate (product) water passes through the membrane and has reduced contaminant concentration. A reject flow stream is produced that contains salts and other constituents rejected by the membrane process.

Review Period –The 30-day period allocated for comments from stakeholders on project Technical Memorandums (TMs). The review period for the CEQA Substitute Environmental Document (SED) is 45 days.

Saline Plumes – Seawater-impacted areas in the groundwater basin that were caused by historical over-pumping which created a hydraulic gradient that resulted in seawater intrusion. These large plumes of saline water are trapped inland of the barrier injection wells, thereby degrading significant volumes of groundwater with high concentrations of chloride and decreasing the ability of affected aquifers to provide groundwater storage.

Salt and Nutrient Management Plan (SNMP) Assistance Document – On June 28, 2012, the Los Angeles Regional Water Quality Control Board issued the *Regional Water Board Assistance in Guiding Salt and Nutrient Management Plan Development in the Los Angeles Region* (SNMP

Assistance Document), which provided guidance for preparation of SNMPs within the Los Angeles region.

Salts and Nutrients – The dissolved ions in water that reflect its salts and nutrients and include calcium, magnesium, sodium, potassium, chloride, fluoride, nitrate, bicarbonate, carbonate, iron, boron, manganese, and phosphate. For the SNMP, total dissolved solids (TDS), chloride, and nitrate have been determined to be the most appropriate indicators of salts and nutrients in the Central Basin and West Coast Basin. See definition for TDS.

Salt and Nutrients Inflows and Outflows – Salt and nutrient inflows and outflows are developed based on the assigning water quality concentrations to the inflows and outflows in the water balance (see definition below). Additional salt and nutrient loading may occur as a result of various water uses, such as fertilizer application. Salt and nutrient loading may also be reduced due to fate and transport processes, e.g. reduction in nitrate due to denitrification and plant uptake.

Secondary Maximum Contaminant Level (SMCL) – Water quality standard established by the State Water Resources Control Board, Division of Drinking Water (formerly the California Department of Public Health) to manage drinking water for aesthetic considerations, such as taste, color, and odor. Contaminants with only SMCLs are not considered to pose a risk to human health.

Self Regenerating Water Softener (SRWS) – A water conditioning device that removes hardness (primarily calcium and magnesium) from water by ion exchange. The calcium and magnesium ions replace sodium or potassium ions on the ion exchange resin. The water softener ion exchange resin is regenerated using salt and results in a brine solution that is flushed to sewers.

Sensitivity Analysis – An analysis that is performed to provide the uncertainty or range of possible future predicted water quality conditions.

Soil Aquifer Treatment – Natural processes that occur in the soil and aquifer that act to filter particulate matter and to remove or reduce chemical and biological constituents of concern to improve groundwater quality.

Source Water – Waters that recharge or flow out of the Central Basin and West Coast Basin and include precipitation, subsurface groundwater inflow from adjacent basins and the ocean, local surface water/stormwater, imported water, recycled water, and wastewater.

Specific Yield – Specific yield is the ratio of the volume of water the aquifer will yield by gravity drainage to the total volume of aquifer and is a measure of the volume of water in the formation.

Stakeholders – Local water and wastewater entities, parties contributing salts and nutrients to groundwater, and parties with an interest in the SNMP process and findings.

Storage Coefficient – The volume of water an aquifer releases from or takes into storage per unit surface area of the aquifer per unit change in head.

Streamlined Permitting for Irrigation Projects – The Recycled Water Policy sets forth criteria for irrigation projects that establish eligibility for streamlined permitting including compliance with the requirements for recycled water established in Title 22 of the California Code of Regulations; application of recycled water at agronomic rates; development and implementation of a site operations and maintenance plan; compliance with any applicable salt and nutrient management plan; and appropriate use of fertilizers.

Study Area – The area of analysis for the Salt and Nutrient Management Plan; it includes all of the Central Basin and West Coast Basin, as defined by the California Department of Water Resources.

Subarea – Smaller areas designated within the groundwater basin to more accurately define the water quality of the basin.

Tertiary Treatment – A treatment process where wastewater that has undergone secondary treatment is processed using granular media or carbon filters and then disinfected.

Time /Concentration Charts – Graphs that show constituent concentrations on the x axis and sampling concentrations on the y axis of an x-y plot and are used to illustrate changes in water quality concentrations over time.

Todd Groundwater Team – Staff from Todd Groundwater (formerly Todd Engineers), RMC Water and Environment, Nellor Environmental Associates Inc., and Environmental Science Associates assisting the Central Basin and West Coast Basin stakeholders in preparing the SNMP.

Total Dissolved Solids (TDS) – An overall measure of the minerals in water. Total salinity is commonly expressed in terms of TDS as milligrams per liter (mg/L). Elevated TDS concentrations above the Secondary Maximum Contaminant Level of 1,000 mg/L are undesirable for aesthetic reasons related to taste, odor, or appearance of the water and not for health reasons; however, elevated TDS concentrations in water can damage crops, affect plant growth, and damage municipal and industrial equipment. For the SNMP, TDS, chloride, and nitrate have been determined to be the most appropriate indicators of salts and nutrients in the CBWCB. See definition for salt and nutrients.

Total Maximum Daily Load (TMDL) – The maximum amount of a pollutant from point sources and nonpoint sources that an impaired water body can receive and still meet water quality standards, within a margin of safety and considering seasonal variation.

Ultraviolet (UV) – UV irradiation is the process by which chemical bonds of the contaminants are broken by the energy associated with UV light (photolysis). UV also has germicidal properties and is used for disinfection.

Unconfined Aquifer – An aquifer in which there are no confining beds between the aquifer and the ground surface. The groundwater surface or water table in an unconfined aquifer is at atmospheric pressure.

Unconformities – A break or gap in the geologic record, such as a break between older eroded bedrock and overlying younger sedimentary units.

Urban Water Management Plans (UWMPs) – Plans prepared by California's urban water suppliers to support their long-term resource planning and ensure adequate water supplies are available to meet existing and future water demands over a 20-year planning horizon considering normal, dry, and multiple dry years. UWMPs are required to be prepared every 5 years and submitted to the California Department of Water Resources.

Vadose Zone – The depth between the land surface and the regional water table. Generally, water in this zone is under less than atmospheric pressure, and some of the voids may contain air or other gases at atmospheric pressure.

Wastewater – Liquid waste discharged from municipal activities, including residential, commercial, and industrial activities. Once treated and discharged from a water reclamation plant, this water becomes recycled water. See definition of Recycled Water.

Water Budget/Balance – An estimate of specific inflows and outflows for each individual basin or sub area and the entire Central Basin and West Coast Basin (CBWCB). Water budgets are extracted from the existing groundwater model of the CBWCB that was previously developed by the United States Geological Services and was recently updated for the Groundwater Basins Master Plan.

Water Quality Averaging Period – The period of time used to determine the existing water quality or representative current concentration of salts and nutrients in groundwater. In accordance with the State Water Resources Control Board (SWRCB) Recycled Water Policy, it is the most recent five years of data, which is the period from mid-2007 to mid-2012 or from January 2007 to January 2012, depending on the data source.

Water Quality Objective (WQO) – Also referred to as Basin Plan Objective (see definition)

Water Year (WY) – The period from October 1 through September 30 of the following year.

West Coast Basin – The California Department of Water Resources (DWR) defines the West Coast Subbasin (DWR Subbasin Number 4-11.03) as occupying a portion (142 square miles) of the Coastal Plain of the Los Angeles Groundwater Basin. In the SNMP, the West Coast "Subbasin" is referred to as the West Coast "Basin." The WRD boundaries encompass all of the DWR defined West Coast Basin extent.

Workplan – In 2011, the *Workplan of the Salt/Nutrient Management Plan* [SNMP]*, Central Basin and West Coast Basin* was prepared by the Central Basin and West Coast Basin (CBWCB) stakeholders and was subsequently approved by the California Regional Water Quality Control Board, Los Angeles Region, on December 13, 2011. The Workplan described the key components and approach for preparation of the SNMP.

AWT – advanced water treatment

NLs – Notification Levels

Remaining Priority Pollutants [a]

Pesticides	Base/Neutral Extractables	Di-n-octyl phthalate
Aldrin	Acenaphthene	Diethyl phthalate
Dieldrin	Benzidine	Dimethyl phthalate
4,4'-DDT	Hexachloroethane	Benzo(a)anthracene
4,4'-DDE	Bis(2-chloroethyl)ether	Benzo(a)fluoranthene
4,4'-DDD	2-chloronaphthalene	Benzo(k)fluoranthene
Alpha-endosulfan	1,3-dichlorobenzene	Chrysene
Beta-endosulfan	3,3'-dichlorobenzidine	Acenaphthylene
Endosulfan sulfate	2,4-dinitrotoluene	Anthracene
Endrin aldehyde	2,6-dinitrotoluene	1,12-benzoperylene
Alpha-BHC	1,2-diphenylhydrazine	Fluorene
Beta-BHC	Fluoranthene	Phenanthrene
Delta-BHC	4-chlorophenyl phenyl ether	1,2,5,6-dibenzanthracene
Acid Extractibles	4-bromophenyl phenyl ether	Indeno(1,2,3-cd)pyrene
2,4,6-trichlorophenol	Bis(2-chloroisopropyl)ether	Pyrene
P-chloro-m-cresol	Bis(2-chloroethoxyl)methane	**Volatile Organics**
2-chlorophenol	Hexachlorobutadiene	Acrolein
2,4-dichlorophenol	Isophorone	Acrylonitrile
2,4-dimethylphenol	Nitrobenzene	Chlorobenzene
2-nitrophenol	n-Nitrosodi-n-propylamine	Chloroethane
4-nitrophenol	n-Nitrosodiphenylamine	1,1-dichloroethylene
2,4-dinitrophenol	Bis(2-ethylhexyl)phthalate	Methyl chloride
4,6-dinitro-o-cresol	Butyl benzyl phthalate	Methyl bromide
Phenol	Di-n-butyl phthalate	2-chloroethyl vinyl ether

a. Frequency for AWT recycled water is quarterly; frequency for groundwater is annually except for Well 34'L-503M where bis(2-ethylhexyl)phthalate and phenanthrene are subject to semi-annual monitoring

AWT – advanced water treatment

Constituents of Emerging Concern [a]
AWT Recycled Water

Parameter	Frequency
17β estradiol	Annually
Caffeine	Annually
n-Nitrosodiphenylamine (NDMA)	Quarterly
Triclosan	Annually
DEET	Annually
Sucralose	Annually

a. Pending availability of laboratory/laboratory method

AWT – advanced water treatment

Water Quality Parameters and Monitoring Frequencies West Coast Basin Seawater Intrusion Barrier

Below are lists of parameters and their respective monitoring frequencies associated with the West Coast Basin Seawater Intrusion Barrier, specifically for advanced treated recycled water produced by WBWMD's Edward C. Little Water Recycling Facility and at the permit-required groundwater monitoring wells.

Inorganics with MCLs

Parameter[a]	Monitoring Frequency for AWT Recycled Water and Groundwater
Aluminum	Quarterly
Antimony	Quarterly
Arsenic	Quarterly
Asbestos	Quarterly
Barium	Quarterly
Beryllium	Quarterly
Cadmium	Quarterly
Chromium	Quarterly
Cyanide	Quarterly
Fluoride	Quarterly
Mercury	Quarterly
Nickel	Quarterly
Nitrate (as NO_3)	Quarterly
Nitrate+Nitrite (sum as nitrogen)	Quarterly
Nitrite (as nitrogen)	Quarterly
Selenium	Quarterly
Thallium	Quarterly

a. Based on Title 22 of the California Code of Regulations, Table 64431-A; at the time the permit was issued, there was no MCL for perchlorate; It was included in the monitoring for Chemicals of Concern to the LARWQCB

AWT – advanced water treatment

MCL – Maximum Contaminant Level

LARWQCB – Los Angeles Regional Water Quality Control Board

Radioactivity MCLs [a]

Parameter	Monitoring Frequency for AWT Recycled Water and Groundwater
Combined Radium-226 and Radium-228	Quarterly
Gross Alpha Particle Activity (Including Radium-226 but excluding Radon and Uranium)	Quarterly
Tritium	Quarterly
Strontium-90	Quarterly
Gross Beta Particle Activity	Quarterly
Uranium	Quarterly

a. Based on Title 22 of the California Code of Regulations, Table 64442
AWT – advanced water treatment
MCLs – Maximum Contaminant Levels

Parameters with Secondary MCLs Consumer Acceptance Limits [a]

Parameter	Monitoring Frequency for AWT Recycled Water and Groundwater

1,2,3-Trichloropropane	Quarterly	Semi-annually
1,2,4-Trimethylbenzene	Quarterly	Semi-annually
1,3,5-Trimethylbenzene	Quarterly	Semi-annually
Vanadium	Quarterly	Semi-annually

a. This was the list of CDPH constituents with NLs at the time the permit was issued
b. Semi-annually for all wells except Well WB-1; frequency for Well WB-1 is monthly

AWT – advanced water treatment

CDPH – California Department of Public Health (now the State Water Resources Control Board, Division of Drinking Water)

NLs – Notification Levels

Remaining Priority Pollutants
(AWT recycled water is monitored quarterly and groundwater monitoring wells are sampled semi-annually)

Pesticides	**Base/Neutral Extractibles**	Di-n-octyl phthalate
Aldrin	Acenaphthene	Diethyl phthalate
Dieldrin	Benzidine	Dimethyl phthalate
4,4'-DDT	Hexachloroethane	Benzo(a)anthracene
4,4'-DDE	Bis(2-chloroethyl)ether	Benzo(a)fluoranthene
4,4'-DDD	2-chloronaphthalene	Benzo(k)fluoranthene
Alpha-endosulfan	1,3-dichlorobenzene	Chrysene
Beta-endosulfan	3,3'-dichlorobenzidine	Acenaphthylene
Endosulfan sulfate	2,4-dinitrotoluene	Anthracene
Endrin aldehyde	2,6-dinitrotoluene	1,12-benzoperylene
Alpha-BHC	1,2-diphenylhydrazine	Fluorene
Beta-BHC	Fluoranthene	Phenanthrene
Delta-BHC	4-chlorophenyl phenyl ether	1,2,5,6-dibenzanthracene
Acid Extractibles	4-bromophenyl phenyl ether	Indeno(1,2,3-cd)pyrene
2,4,6-trichlorophenol	Bis(2-chloroisopropyl)ether	Pyrene
P-chloro-m-cresol	Bis(2-chloroethoxyl)methane	**Volatile Organics**
2-chlorophenol	Hexachlorobutadiene	Acrolein
2,4-dichlorophenol	Isophorone	Acrylonitrile
2,4-dimethylphenol	Nitrobenzene	Chlorobenzene
2-nitrophenol	N-nitrosodi-n-propylamine	Chloroethane
4-nitrophenol	N-nitrosodiphenylamine	1,1-dichloroethylene
2,4-dinitrophenol	Bis(2-ethylhexyl)phthalate	Methyl chloride
4,6-dinitro-o-cresol	Butyl benzyl phthalate	Methyl bromide
Phenol	Di-n-butyl phthalate	2-chloroethyl vinyl ether

AWT – advanced water treatment

Attachment K-E

Water Quality Parameters and Monitoring Frequencies Dominguez Gap Seawater Intrusion Barrier

Below are lists of parameters and their respective monitoring frequencies associated with the Dominguez Gap Seawater Intrusion Barrier, specifically for advanced treated recycled water produced by the City of Los Angeles' Terminal Island Water Reclamation Plant / Advanced Water Purification Facility (TIWRP), blended and delivered recycled water/imported water, and at the permit-required groundwater monitoring wells.

Advanced Treated Recycled Water Monitoring

Parameter	Frequency
Flow	Daily
Turbidity	Daily
Chlorine residual	Daily
pH	Daily
Total coliform	Daily
Total organic carbon	4X/Month
Temperature	At least weekly
Total nitrogen	2X/Week
Ammonia	2X/Week
Organic nitrogen	2X/Week
Nitrite	2X/Week
Nitrate	2X/Week

Blended Water

Parameter	Frequency
Flow	Daily
Total dissolved solids	Weekly
Sulfate	Weekly
Chloride	Weekly
Boron	Weekly
Total nitrogen	2X/Week

Delivered Water

Parameter	Frequency
Methyl tertiary butyl ether	Monthly
Tert-butyl alcohol	Monthly
N-nitrosodimethlyamine	Quarterly
General Physical/Mineral & Inorganic Chemicals	
Aluminum	Quarterly
Aluminum	Quarterly
Antimony	Quarterly
Arsenic	Quarterly
Asbestos	Quarterly
Barium	Quarterly
Beryllium	Quarterly
Cadmium	Quarterly
Calcium	Quarterly
Chromium	Quarterly
Color	Quarterly
Copper	Quarterly
Cyanide	Quarterly
Fluoride	Quarterly
Foaming agents	Quarterly
Iron	Quarterly
Manganese	Quarterly
Mercury	Quarterly
Nickel	Quarterly
Nitrate	Quarterly
Odor	Quarterly
Potassium	Quarterly
Selenium	Quarterly
Silver	Quarterly
Sodium	Quarterly
Specific conductance	Quarterly
Thallium	Quarterly
Total hardness	Quarterly
Zinc	Quarterly

Radioactivity

Parameter	Frequency
Combined Radium-226 and Radium-228	Quarterly
Gross Alpha Particle Activity (Including Radium-226 but Excluding Radon and Uranium)	Quarterly
Tritium	Quarterly
Strontium-90	Quarterly
Gross Beta Particle Activity	Quarterly
Uranium	Quarterly

Volatile Organic Chemicals

Parameter	Frequency
Benzene	Quarterly
Carbon Tetrachloride	Quarterly
1,2-Dichlorobenzene	Quarterly
1,4-Dichlorobenzene	Quarterly
1,1-Dichloroethane	Quarterly
1,2-Dichloroethane	Quarterly
1,1-Dichloroethylene	Quarterly
cis-1,2-Dichloroethylene	Quarterly
trans-1,2-Dichloroethylene	Quarterly
Dichloromethane	Quarterly
1,2-Dichloropropane	Quarterly
1,3-Dichloropropene	Quarterly
Ethylbenzene	Quarterly
Methyl-*tert*-butyl ether	Quarterly
Monochlorobenzene	Quarterly
Styrene	Quarterly
1,1,2,2-Tetrachloroethane	Quarterly
Tetrachloroethylene	Quarterly
Toluene	Quarterly
1,2,4-Trichlorobenzene	Quarterly
1,1,1-Trichloroethane	Quarterly
1,1,2-Trichloroethane	Quarterly
Trichloroethylene	Quarterly
Trichlorofluoromethane	Quarterly
1,1,2-Trichloro-1,2,2-Trifluoroethane	Quarterly
Vinyl Chloride	Quarterly
Xylenes	Quarterly

Non-Volatile Synthetic Organic Chemicals

Parameter	Frequency
Alachlor	Quarterly
Atrazine	Quarterly
Bentazon	Quarterly
Benzo(a)pyrene	Quarterly
Carbofuran	Quarterly
Chlordane	Quarterly
2,4-D	Quarterly
Dalapon	Quarterly
Dibromochloropropane	Quarterly
Di(2-ethylhexyl)adipate	Quarterly
Di(2-ethylhexyl)phthalate	Quarterly
Dinoseb	Quarterly
Diquat	Quarterly
Endothall	Quarterly
Endrin	Quarterly
Ethylene Dibromide	Quarterly
Glyphosate	Quarterly
Heptachlor	Quarterly
Heptachlor Epoxide	Quarterly
Hexachlorobenzene	Quarterly
Hexachlorocyclopentadiene	Quarterly
Lindane	Quarterly
Methoxychlor	Quarterly
Molinate	Quarterly
Oxamyl	Quarterly
Pentachlorophenol	Quarterly
Picloram	Quarterly
Polychlorinated Biphenyls	Quarterly
Simazine	Quarterly
Thiobencarb	Quarterly
Toxaphene	Quarterly
2,3,7,8-TCDD (Dioxin)	Quarterly
2,4,5-TP (Silvex)	Quarterly

Disinfection Byproducts

Parameter	Frequency
Total trihalomethanes (TTHM)	Quarterly
Bromodichloromethane	
Bromoform	
Chloroform	
Dibromochloromethane

MWD Compliance Plan

THE METROPOLITAN WATER DISTRICT OF SOUTHERN CALIFORNIA

Office of the General Manager

March 3, 2011

Kurt Souza
California Department of Public Health
Drinking Water Field Operations Branch
1180 Eugenia Place, Suite 200
Carpinteria, CA 93013

Reply to: 700 Moreno Avenue
La Verne, CA 91750

System No. 1910087

Dear Mr. Souza:

Chemical Compliance Monitoring Plan, Compliance Cycle 2011–2019

Per CDPH recommendations, the Small Systems Chemical Compliance Monitoring has been removed from this plan.

Metropolitan Water District of Southern California (Metropolitan) is submitting a chemical compliance monitoring plan for your review and approval. Changes to the plan include reducing nitrate monitoring to annually because all quarterly results have been < ½ the MCL of 10 mg/L as nitrogen for the past year. Nitrite monitoring will be reduced to annually because all results have been < ½ the MCL of 1.0 mg/L for the past year. Also, asbestos monitoring will be reduced from annually to once per 9 year compliance cycle. The plan addresses the following constituents: inorganic chemicals, organic chemicals, radiologicals, general mineral, and general physical parameters for compliance cycle 3 (2011–2019). The sampling sites include Metropolitan's source waters, treatment plant influents, and treatment plant effluents (entry points to the distribution system). The monitoring information for disinfection by-products (DBPs) and DBP precursors can be found in the most recently submitted DBP Monitoring Plan.

Submittal of this document satisfies the chemical compliance monitoring plan requirement of California Code of Regulations Title 22, section 64416. If you have any questions, please call me at (909) 392-5081.

Sincerely,

Melissa Dale

COMPLIANCE MONITORING PLAN

METROPOLITAN WATER DISTRICT OF SOUTHERN CALIFORNIA

System No. 1910087
January 2011

DESCRIPTION OF SYSTEM

The Metropolitan Water District of Southern California (Metropolitan) is a public, municipal corporation of the State of California. Metropolitan is a consortium of 26 cities and water districts that provides drinking water to nearly 19 million people in parts of Los Angeles, Orange, San Diego, Riverside, San Bernardino, and Ventura counties. Water is imported from the Colorado River via Metropolitan's Colorado River Aqueduct and from northern California via the State Water Project's Edmund G. Brown California Aqueduct. This water is supplied within a 5,200 square mile service area through Metropolitan's 26 member agencies and 150 sub-agencies.

Metropolitan utilizes a total of seven reservoirs for storing untreated source waters (Figure 1). Three reservoirs store the State Project water (SPW): Castaic Lake (West Branch), Silverwood Lake (East Branch), and Lake Perris (East Branch). Four reservoirs store the Colorado River water (CRW) or a blend of CRW and SPW: Lake Havasu (CRW), Lake Mathews (CRW or blend), Lake Skinner (blend), and Diamond Valley Lake (blend).

Metropolitan operates five treatment plants (Jensen, Weymouth, Diemer, Mills, and Skinner; Figure 1) by conventional treatment, with the exception of Skinner filtration plant No. 2, which uses direct filtration. Jensen and Mills water treatment plants treat the West Branch and East Branch SPW, respectively. Diemer and Weymouth filtration plants treat CRW or a blend of CRW and East Branch SPW from Lake Mathews and Silverwood Lake. Skinner filtration plant treats water from Lake Skinner, which is capable of receiving water from the Colorado River Aqueduct, and East Branch SPW from Silverwood Lake, Lake Perris, or Diamond Valley Lake (DVL).

CHEMICAL COMPLIANCE MONITORING PROGRAM

The U.S. Environmental Protection Agency (USEPA) and State of California Department of Public Health (CDPH) regulations require monitoring of Metropolitan's source and finished water for general mineral, general physical, cyanide, foaming agents, trace metals, pesticides, herbicides, synthetic organic compounds (SOCs), volatile organic compounds (VOCs), disinfection by-products (DBPs), DBP precursors, disinfectants, asbestos, and radiological constituents. Title 22 of the Health and Safety code requires samples to be collected from each water source (except for DBP related constituents), or from the point of entry into the distribution system that is representative of each water source after treatment. Table 1 lists the compliance sites, source water/point of entry, CDPH station location number, latitude, and longitude. Several sites (Lake Havasu, San Jacinto Tunnel West Portal, and Lake Mathews) along the CRW aqueduct system were chosen to characterize the water quality along the aqueduct. Two terminal reservoirs (Castaic Lake and Silverwood Lake) of the SPW system, along with an emergency source (Lake Perris), are sampled. Lake Perris is used only occasionally and samples will be collected from the lake effluent when water is being withdrawn and from the outlet tower at 9 m when the water is not being withdrawn. Lake Skinner and DVL are also sampled. DVL will be sampled from the inlet/outlet structure when water is flowing out of the lake and near the outlet tower in the west basin at 12 m when water is not flowing out. Smaller raw water reservoirs (Live Oak Reservoir and Etiwanda) located within Metropolitan's system are not sampled because they are considered protected from any outside influence and changes in water quality (i.e., related to regulated and required unregulated contaminants) are not expected. Each treatment plant effluent is sampled and represents the point of entry into the distribution system.

The CDPH required monitoring schedule is based on a "Compliance Cycle" defined as a nine calendar year cycle (Table 2). Each compliance cycle is divided into three 3-year compliance periods. The initial compliance cycle was completed on December 31, 2001. Monitoring for the second compliance cycle will be completed December 31, 2010. Table 3 shows the monitoring requirements for each analytical group. Table 4 shows Metropolitan's compliance and voluntary monitoring schedule, by analytical group, through the third compliance cycle (ending 2019). **All monitoring listed in Table 4 will be reported to CDPH via the Write-On Electronic Data Transfer program.**

Most of the secondary standards are analyzed along with a regulated group. Methyl *tert*-butyl ether is included with the VOC group. Thiobencarb, which also has a primary standard, is measured with the SOCs. General mineral/general physical analysis includes chloride, color, specific conductance, sulfate, total dissolved solids, and turbidity. Trace metals analysis captures aluminum, copper, iron, manganese, silver, and zinc. The remaining secondary standards—foaming agents (MBAS) and odor threshold—are analyzed by specific methods.

Metropolitan continues to monitor for several of the California Unregulated Contaminant Monitoring Regulation (UCMR) compounds, which are no longer required. The gasoline additives ethyl-*tert* butyl ether, tert-amyl methyl ether, and tert-butyl alcohol are measured with the VOC group. Boron and vanadium are included in the trace metals analysis. Hexavalent chromium is analyzed by a compound-specific method.

Initial monitoring for the Federal UCMR cycles 1 and 2 compounds was completed between 2001–2003 and 2008–2009, respectively. Follow-up monitoring for the Federal UCMR is not required; additional monitoring will be implemented when the next cycle of the Federal UCMR (UCMR 3) is promulgated.

D/DBP RULE MONITORING

Disinfectants, DBPs, and DBP precursors are monitored in compliance with the USEPA D/DBP Rule (refer to the most recently submitted D/DBP Monitoring Plan).

METROPOLITAN'S TASTE AND ODOR MONITORING PROGRAM

Metropolitan maintains a proactive monitoring program for taste and odor control. Samples are analyzed by a group of trained panelists by the flavor profile analysis (FPA) technique. At least once each week, the panel monitors treatment plant samples. In addition, the treatment plant laboratory personnel conduct daily FPA screenings. Also, the panel monitors selected distribution locations on a weekly basis. Threshold odor numbers are determined annually for compliance with the secondary standard for odor.

Table 1. Metropolitan Water District of Southern California (System Number 1910087) Monitoring Sample Sites

Primary Station Code	Sample Location	Source Water/ Treated Water	Station Location #	Latitude	Longitude
	COMPLIANCE LOCATIONS				
016	Devil Canyon Afterbay Silverwood Lake	Effluent from Silverwood Lake	G19/087-SLDCAFB	[redacted]	[redacted]

C - Compliance monitoring
V –Voluntary monitoring

* Lead and copper is only performed on Metropolitan's domestic water systems – see Small Systems Monitoring Plan for details
# Aluminum will be analyzed and reported monthly for the treatment plant effluent when alum is used as the coagulant.
† Additional fluoride monitoring at the treatment plant effluents is reported under Metropolitan's Fluoride Plan.

Figure 1. Metropolitan's Service Area

Attachment K-I

Los Angeles Department of Water and Power (LADWP) Imported Water Monitoring

Presented below is the Vulnerability Assessment and Monitoring Program for imported water treated at the Los Angeles Aqueduct Filtration Plant based on the November 2012 Annual Water Quality Report Data Source (Master) Table.

Contaminants	Sampling Frequency
General Contaminants	Quarterly
Gross Beta, Ra-226/228, Strontium-90, Tritium & Uranium	Quarterly
pH, Specific Conductance, Temperature, Total Chlorine Residual – Source Water Locations	Daily, Weekly
Total Coliform, *E. Coli*, Fecal Coliform - Source Water Locations	Daily
Total Trihalomethanes and Haloacetic Acids	Monthly
Synthetic Organic Chemicals	2 Consecutive quarters / 3-yr cycle
Gross Alpha – Source Water Locations	6-yr cycle
Cryptosporidium and *Giardia*	Monthly
Asbestos	9-yr cycle
Radon	Annually
Arsenic	Weekly
Bromate	Weekly
Turbidity (Primary Standard)	On-line (continuous)
Total Coliform, E. Coli, and Fecal Coliform – Distribution Locations	Daily
Total Chlorine Residual – Same Locations as TCR Sampling	Daily
Lead and Copper (at-the-tap) – Residences	3-yr cycle
Fluoride	Daily
Total Trihalomethanes and Haloacetic Acids – 20 Locations	Monthly
Bromate (Opened Reservoir)	Weekly
Cryptosporidium and *Giardia* (Opened Reservoir)	Bi-weekly
Individual THMs and HAAs – Area-wide distributions system	Monthly
Chlorate	Daily

San Gabriel River Regional Monitoring Program (SGRRMP)

During 2009-2010, the following participants contributed staff time, laboratory analyses, and funding in a collaborative effort to implement the San Gabriel River Regional Monitoring Program (SGRRMP). As shown in the list below, participants included representatives from regulated entities, regulatory agencies, environmental groups, and research organizations. A majority of the funding was provided by SDLAC.

- SDLAC
- Council for Watershed Health
- City of Downey
- Los Angeles County Flood Control District
- LARWQCB
- Orange County Stormwater Program
- Southern California Coastal Water Research Project
- USEPA
- Participating Consultants
- Aquatic Bioassay and Consulting Laboratories
- Institute for Integrated Research in Materials, Environments, and Society California State University, Long Beach,
- Weston Solutions
- Weck Laboratories

Below is a list of parameters and their monitoring frequencies for the SGRRMP.

Freshwater Constituents

Parameter
Temperature
pH
Conductivity
Dissolved Oxygen
Salinity
Alkalinity
Hardness
Total Suspended Solids
Chlorophyll a
Ash-free dry mass
Dissolved Organic Carbon
Total Organic Carbon
Ammonia
Nitrate
Nitrite
Total Kjeldahl Nitrogen

Parameter
Total Nitrogen
Orthophosphate
Phosphorus
Chloride
Sulfate
Silica
Trace metals (total and dissolved): Arsenic, Cadmium, Chromium, Copper, Iron, Mercury, Lead, Nickel, Selenium, Zinc
Organophosphorus Pesticides
Pyrethroids Pesticides
Chronic Toxicity - Ceriodaphnia dubia (freshwater): primary test organism; Chronic Hyallela azteca (freshwater): secondary test organism if conductivity is > 2,500 µS/cm
Taxonomy: Benthic Macroinvertebrate, Qualitative Algae, Quantitative Diatom, Quantitative Algae

Table 1. Summary of the SGRRMP watershed monitoring program designed to address each of the five core management questions.

Question	Approach	Sites	Indicators	Frequency
Q1: Stream condition	Randomized design for streams in entire watershed	30 in year 1 (2005) 10 new in each following year	Triad: bioassessment (BMI & attached algae), water chemistry, toxicity, CRAM	Annually, in spring
Q2: Unique areas	Fixed sites in estuary and freshwater	12 in freshwater • 4 high[1] value wetlands • 8 target sites: 5 confluence of tribs/mainstem & 3 background	Freshwater: • Wetland habitat (CRAM) • Target sites: bioassessment (BMI), water chemistry, toxicity, CRAM	 Annually, in summer Annually, in spring
		4 in estuary	Estuary: • Full suite water quality • Sediment chemistry, toxicity, infauna	 Annually, in summer Annually, in summer
Q3: Discharges	Assess NPDES receiving water results against water quality standards	NPDES receiving water sampling locations	Water quality, chemistry, toxicity, bioassessment, bacteria	Varies
Q4: Safe to swim	Focus on high use areas	8 upper watershed river sites 5 lower watershed sentinel sites 1 estuary	• *E. coli* • *E. coli* • Total coliforms, *E. coli*, Enterococcus	5 samples/month (May to Sept) 5 samples/month (May to Sept) 2 samples/week (throughout year)
Q5: Safe to eat fish	Focus on: • Popular fishing sites • Commonly caught species • High risk chemicals	Rotate popular fishing locations: two sites per year	Commonly caught fish at each location Mercury, DDTs, PCBs, arsenic, selenium	Annually in late summer

[1] High value sites are locations of relatively isolated unique habitat.

Attachment K-K

Los Angeles River Watershed Monitoring Program (LARWMP)

During 2009-2010, the following participants contributed staff time, laboratory analyses, and funding in a collaborative effort to implement the Los Angeles River Watershed Monitoring Program (LARWMP). As shown in the list below, participants that included representatives from regulated entities, regulatory agencies, environmental groups, and research organizations. A majority of the funding was provided by the Cities of Los Angeles and Burbank and the Los Angeles County Department of Public Works (LACDPW).

- Arroyo Seco Foundation
- City of Burbank
- City of Downey
- City of Los Angeles
- Friends of the Los Angeles River
- LACDPW
- LARWQCB
- Los Angeles & San Gabriel Rivers Watershed
- Council for Watershed Health
- San Gabriel Mountains and Rivers Conservancy
- Southern California Coastal Water Research Project
- USEPA
- U.S. Forest Service
- Aquatic Bioassay and Consulting Laboratories
- Brock Bernstein Consultant

Below is a list of parameters and their monitoring frequencies for the LARWMP.

Freshwater Constituents

Parameter
Temperature
pH
Conductivity
Dissolved Oxygen
Salinity
Alkalinity
Hardness
Total Suspended Solids
Dissolved Organic Carbon
Total Organic Carbon
Ammonia
Nitrate
Nitrite
Total Kjeldahl Nitrogen

Parameter
Total Nitrogen
Orthophosphate
Phosphorus
Chloride
Sulfate
Silica
Trace metals (total and dissolved): Arsenic, Cadmium, Chromium, Copper, Iron, Mercury, Lead, Nickel, Selinium, Zinc
Organophosphorus Pesticides
Pyrethroids Pesticides
Chronic Toxicity - Ceriodaphnia dubia (freshwater): primary test organism; Chronic Hyallela azteca (freshwater): secondary test organism if conductivity is > 2,500 µS/cm
Taxonomy: Benthic Macroinvertebrate, Qualitative Algae, Quantitative Diatom, Quantitative Algae

Table 1. Monitoring design, indictors and sampling frequency.

Question	Approach	Sites	Indicators	Frequency
Q1: What is the condition of streams?	Randomized design for streams in entire watershed, except 1st and 2nd order[1] streams Streams assigned to natural, effluent dominated, urban runoff dominated subpopulations	10 randomly selected each year	Triad: bioassessment, physical habitat, CRAM, water chemistry, toxicity	Annually, in spring
Q2: What is the trend of condition at unique areas?	Fixed stations in estuary and freshwater	12 (approx.) in freshwater • 5 (approx.) high[2] value • 4 confluence of tribs/mainstem • 1 or 2 background	Freshwater • Riparian habitat using CRAM • Triad: bioassessment, water chemistry, toxicity • Riparian habitat using CRAM	 Annually, in spring Annually, in spring Annually, in spring
		1 in estuary	Estuary • Conventional water quality • Full suite water quality • Sediment chemistry, toxicity, infauna	 Not determined Annually Annually
Q3: Are receiving waters near discharges meeting objectives?	Use existing NPDES water quality data collected by LA River dischargers from receiving waters upstream and downstream of their discharge points	Sites located upstream and downstream of discharges. • Los Angeles/Glendale • City of Burbank • Tillman Water Reclamation Plant	Constituents with established water quality standards, e.g. CTR for dissolved metals, e. coli bacteria	Varies depending on permit monthly, quarterly, annual
Q4: Is it safe to swim?	Focus on high-use areas	6 – 10 in river 9 sentinel	E. coli	Weekly in swim season
		15 beach	Total & fecal coliforms, *Enterococcus*	Weekly year round
Q5: Is it safe to eat locally caught fish?	Focus on: • Popular fishing sites • Commonly caught species • High risk chemicals	3 lakes 2 river 1 estuary	Commonly caught fish at each location Mercury, Selenium, DDTs, PCBs,	Annually in summer

[1] Stream order is defined by a tributary's position in the branching network, with 1st order streams being headwater streams, 2nd order streams those with one tributary above them, and so on.

[2] High value sites are locations of relatively isolated unique habitat

Attachment K-L

LACDPW MS4 Stormwater Monitoring

Below are details on the Los Angeles County Department of Public Work's (LACDPW's) stormwater monitoring program, which is conducted in accordance with the NPDES permit for municipal separate storm sewer system (MS4) discharges for 84 cities and a majority portion of the unincorporated areas of Los Angeles County.

<u>Mass Emission Stations (MES) in the CBWCB SNMP Study Area</u>

Los Angeles River Monitoring Station (S10)

Monitoring Station S10 is located in the Los Angeles River at the existing stream gauge station (specifically, Stream Gauge F319-R) between Willow Street and Wardlow Road in the City of Long Beach and was chosen to avoid tidal influences. The Los Angeles River is a concrete-lined trapezoidal channel at this station. The total upstream tributary drainage area for the Los Angeles River is 825 square miles. This river is the largest watershed outlet to the Pacific Ocean in the Los Angeles County Flood Control District (LACFCD). This station can be found in the Thomas Guide, page 795, C-1.

Coyote Creek Monitoring Station (S13)

Monitoring Station S13 is located in Coyote Creek at the existing U.S. Army Corps of Engineers (USACE) stream gauge station (specifically, Stream Gauge F354-R) below Spring Street in the lower San Gabriel River Watershed. The station assists in determining mass loading for the San Gabriel River Watershed. The upstream tributary area is 150 square miles and extends into Orange County. The station was chosen to avoid backwater effects from the San Gabriel River to ensure that all water being sampled is from Coyote Creek only. Coyote Creek is a concrete-lined trapezoidal channel at this location. This Coyote Creek MES location has been an active stream gauging station since 1963. This station can be found in the Thomas Guide, page 796, grid H-2.

San Gabriel River Monitoring Station (S14)

Monitoring Station S14 is located in the San Gabriel River at a historic stream gauge station (specifically, Stream Gauge F263C-R) below San Gabriel River Parkway in Pico Rivera. The upstream tributary area is 450 square miles at this location. At this monitoring location, the San Gabriel River is a grouted rock concrete stabilizer along the western levee and a natural section on the eastern side. Flow measurement and water sampling are conducted in the grouted rock area along the western levee of the river. The length of the concrete stabilizer is nearly 70 ft. This San Gabriel River MES location has been an active stream gauging station since 1968. This station can be found in the Thomas Guide, page 676, J-2.

Tributary Stations within the CBWCB SNMP Study Area (that have been monitored through 2011-12)

Monitoring started in 2002

Annual Monitoring: Rio Hondo Channel

Rotating Monitoring:

- Los Angeles River Watershed: Aliso Creek, Bull Creek, Burbank Western System Channel, Verdugo Wash, Arroyo Seco Channel (2002-2003 and 2003-2004 storm seasons)
- San Gabriel River Watershed: Big Dalton\Walnut Creek, Puente Creek, Upper San Jose Creek, Maplewood Channel, North Fork Coyote, and SD 21 (Artesia-Norwalk Drain) (2006-2007 and 2007-08 storm seasons)

Constituents for the Stormwater Monitoring Program and Associated Minimum Levels [a]

PARAMETER	MINIMUM LEVEL
CONVENTIONAL POLLUTANTS	**mg/L**
Oil and Grease	5
Total Phenols	0.1

All constituents for which the water body is impaired downstream of the monitoring station	

a - For Priority Pollutants, the MLs represent the lowest value listed in Appendix 4 of the State Implementation Plan: Method Detection Limits must be lower than or equal to the ML value; if a particular ML is not attainable in accordance with procedures set forth in 40 Code of Federal Regulations 136, the lowest quantifiable concentration of the lowest calibration standard analyzed by a specific analytical procedure may be used instead

MDL – method detection limit
mg/L – milligrams per liter
ML – minimum level
MPN – most probably number
NTU - Nephelometric Turbidity Unit
ug/L – micrograms per liter
umho/cm – micromhos per centimeter

Monitoring for Non-Stormwater Releases

Discharges from drinking water supplier distribution systems >100,000 gallons must monitor in the release for pollutants of concern defined as: trash and debris, including organic matter, total suspended solids, residual chlorine, pH, and any pollutant for which there is a water quality-based effluent limitation applicable to discharges from the MS4 to the receiving water. Determination of the pollutants of concern for a particular discharge shall be based on an evaluation of the potential for the constituent(s) to be present in the discharge at levels that may cause or contribute to exceedances of applicable water quality based effluent limits or receiving water limitations.

Discharge from lake dewatering must monitor in the release for pollutants of concern defined as: at a minimum, trash and debris, including organic matter, total suspended solids, and any pollutant for which there is a water quality-based effluent limitation for the lake and/or receiving water.

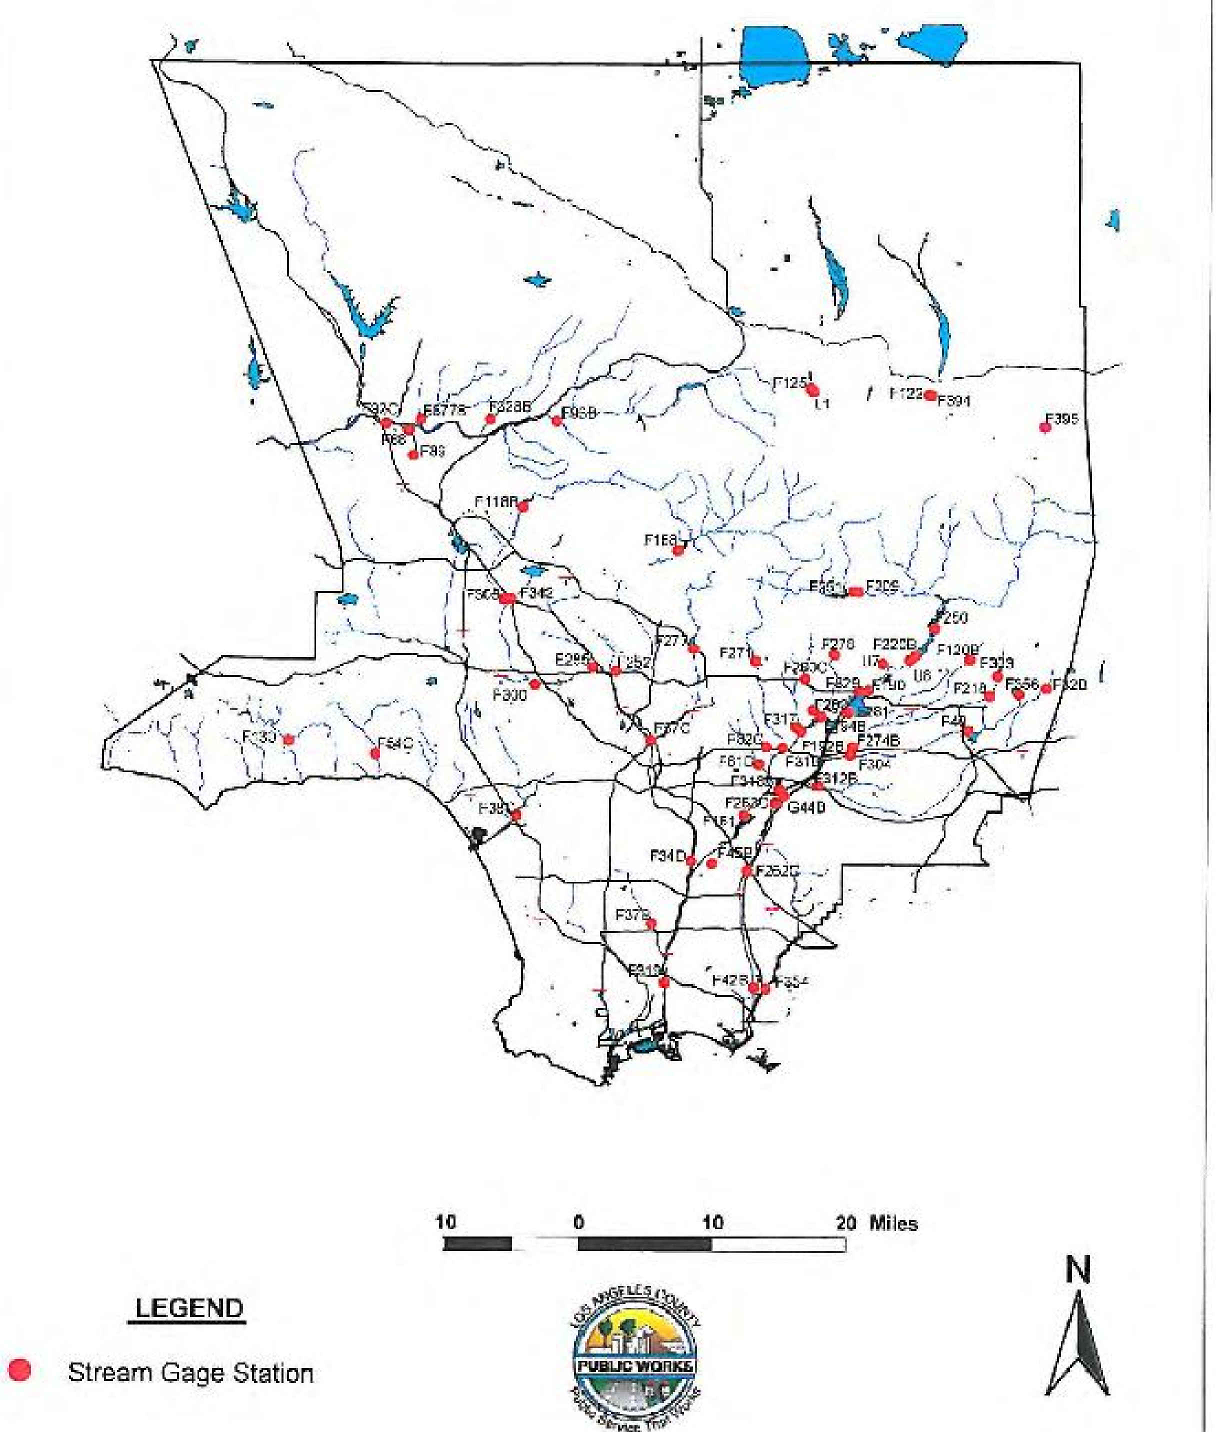
Attachment K-M

LACDPW Stream Gauge Flow Monitoring

RUNOFF

STREAM GAGE STATION LOCATIONS



RUNOFF

Public Works operated 62 stream gaging stations during the 2009-10 water year. Mean daily flow and maximum instantaneous flow rates for each station are summarized and published in this volume. Annual summaries of peak flows and volumes are also provided. Additional data can be obtained by contacting the custodian of hydrologic records.

LEGEND

Stations are designated by letters and numbers which indicate ownership, operation agency, and type of station.

- Prefix **F** - Indicates a station originally owned and operated by the Los Angeles County Flood Control District and now owned and operated by Public Works.
- Prefix **E** - Indicates a station owned by the U.S. Army Corps of Engineers, but operated and maintained by the U.S. Geological Survey.
- Prefix **U** or **G** - Indicates a station originally constructed and operated by the U.S. Geological Survey, but now operated by Public Works.
- Prefix **L** - Indicates a station formerly owned by the Little Rock Water District, but now owned and operated by Public Works.
- Suffix **R** - Indicates a recorder station.
- Suffix **B, C** - Indicates that the station has been moved from its original location. B represents second location, C a third location, etc.

ALERT SYSTEM
Automated Local Evaluation in Real Time

Public Works operates and maintains the ALERT computer system to monitor meteorological conditions at 24 river stage locations in the County. Public Works' ALERT System also receives rainfall, streamflow, and reservoir data from the Corps of Engineers' Los Angeles Telemetry System.

COOPERATION

Public Works receives or has access to stream flow data from other agencies. Public Works exchanges data with the following agencies:

- U.S. Geological Survey, Water Resource Division
- U.S. Army Corps of Engineers
- State Department of Water Resources
- The Metropolitan Water District of Southern California
- San Gabriel River Water Committee

REGIONAL GROUNDWATER MONITORING PROGRAM (RGWMP) PLAN
Central Basin and West Coast Basin (CBWCB)
Southern Los Angeles County, California
April 2014

The Water Replenishment District of Southern California (WRD) manages groundwater replenishment and monitors water quality of the Central Basin and West Coast Basin (CBWCB) in southern Los Angeles County (see **Figure 1** below). Our mission is to protect and preserve high-quality groundwater in the basins through innovative, cost-effective, and environmentally sensitive management practices for the benefit of residents and businesses of the CBWCB. As part of accomplishing this mission, WRD implemented the Regional Groundwater Monitoring Program (RGWMP) to provide a comprehensive and current understanding of groundwater conditions in the CBWCB in order to predict and prepare for future conditions. This Plan describes the RGWMP.

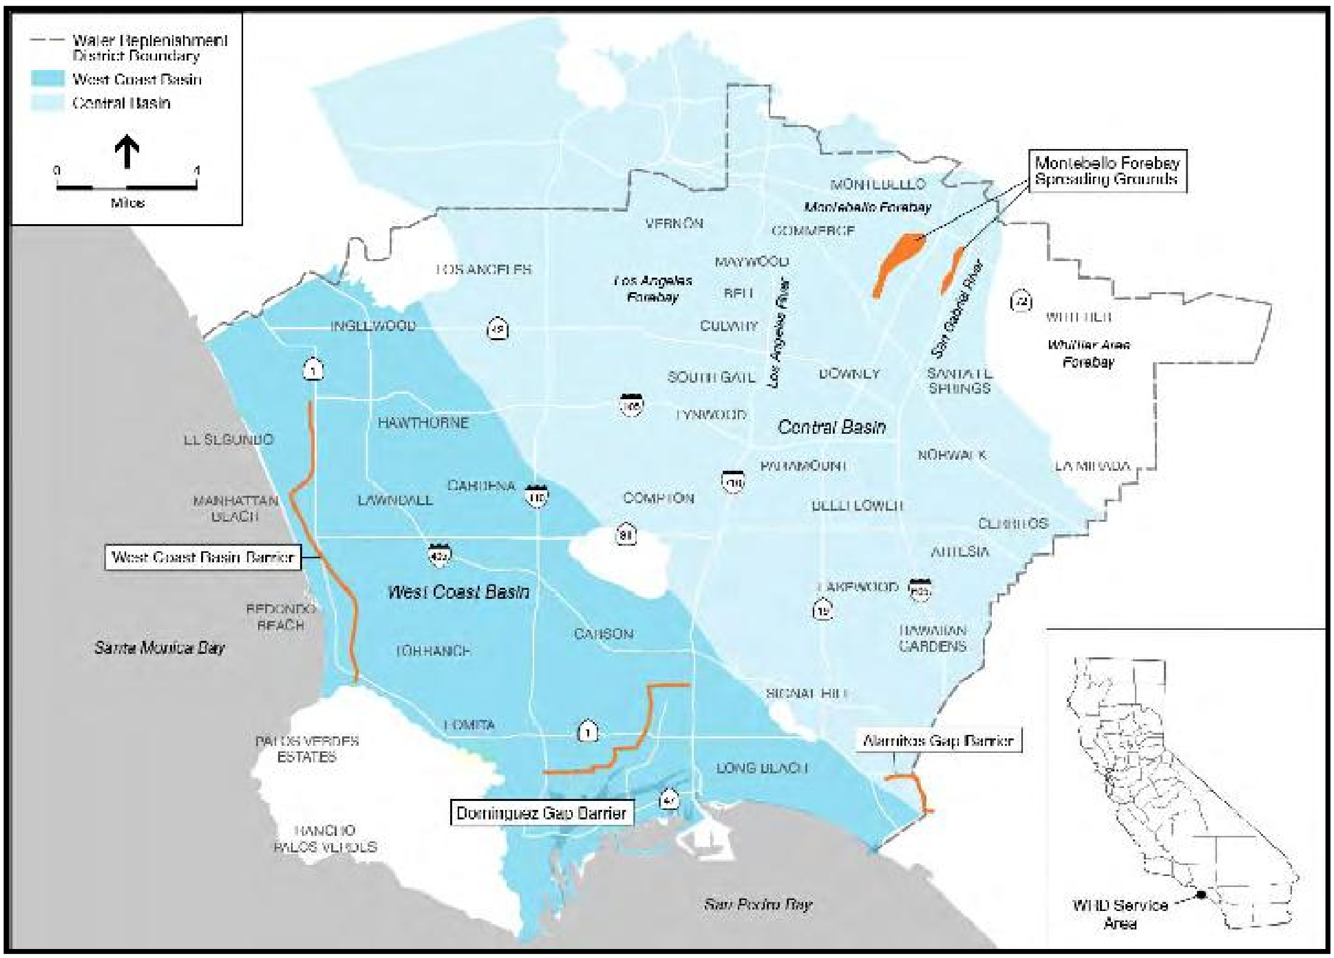

FIGURE 1
West Coast Basin and Central Basin, Southern Los Angeles County

I. BACKGROUND

Between the 1900s and 1950s, groundwater was an important factor in urbanization of the CBWCB. Historical over pumping of the CBWCB caused overdraft, seawater intrusion, and other groundwater management problems related to supply and quality. To remedy these problems, the courts adjudicated the two basins in the early 1960s and set a limit on allowable groundwater production in order to control the over pumping. The California Department of Water Resources (DWR) was established as Watermaster of the CBWCB and is responsible for tracking groundwater extraction volumes.

Concurrent with the adjudication of the CBWCB, WRD was formed by a vote of the people in 1959 for the purpose of protecting the groundwater resources of the CBWCB. Since its formation, WRD has been actively involved in groundwater replenishment, water quality monitoring, contamination prevention, data management, and data publication. WRD protects the basins through groundwater replenishment, deterrence of seawater intrusion, and groundwater quality monitoring of contamination through an assessment on water pumped from the WRD service area. WRD ensures that a reliable supply of high-quality groundwater is available through its clean water projects, water supply programs, and effective management principles.

During Water Year (WY) 1994-95, WRD and the United States Geological Survey (USGS) began a cooperative study to improve the understanding of the geohydrology and geochemistry of the CBWCB. The initial study was documented in the USGS Water Resources Investigations Report 03-4065, *Geohydrology, Geochemistry and Ground-Water Simulation-Optimization of the Central Basin and West Coast Basin, Los Angeles County, California* (Reichard et al. 2003). In addition to compiling existing available data, this study recognized that the sampling of production wells did not adequately characterize the layered multiple aquifer systems of the CBWCB. The study focused on new data collection techniques including drilling and construction of nested groundwater monitoring wells and conducting depth-specific water quality monitoring. This study is the nucleus of the current and ongoing RGWMP.

1. GOALS AND OBJECTIVES

The protection and enhancement of quality groundwater in the Central and West Coast groundwater basins is a high priority for WRD. As a result, WRD established the RGWMP to improve the framework for understanding the dynamics of the groundwater system and use as a planning tool. The primary goal of the RGWMP is to track regional groundwater levels and groundwater quality in the CBWCB to ensure the continued usability of this beneficial resource. WRD staff, comprised of certified hydrogeologists and registered engineers, provides the in-house capability to collect, analyze, and report the groundwater data.

The RGWMP includes groundwater monitoring, modeling, and planning data, which are used to determine the "health" of the basins. This information in turn provides WRD, the pumpers in the basin, other interested stakeholders, and the public with the knowledge necessary for responsible water resources planning and management. Data collected from the RGWMP are evaluated and presented in annual *Regional Groundwater Monitoring Reports* (RGWMRs), as further discussed in Section VII Annual Reports.

2. GENERAL AND CURRENT GROUNDWATER QUALITY

Between 1900 and the 1950s, groundwater was an important factor in urbanization of the CBWCB. Excessive overpumping in the CBWCB caused severe overdraft and created a hydraulic gradient that resulted in seawater intrusion, which contaminated the coastal groundwater aquifers. To halt the intrusion, three seawater barriers (see Figure 1) were constructed by the Los Angeles County Department of Public Works (LACDPW): the West Coast Basin Barrier Project was initiated in the mid-1950s, the Alamitos Barrier Project in the early 1960s, and the Dominguez Gap Barrier Project in the early 1970s. LACDPW owns and operates all three barrier projects and WRD purchases all the water for injection.

Groundwater quality in the CBWCB also reflects current and historic land uses. There are localized areas of marginal to poor water quality that go untapped or may require treatment prior to use. Historic agricultural activities may have impacted groundwater locally and as an urban developed region, commercial and industrial activities (e.g., leaking aboveground and underground storage tanks, leaking sewer and oil pipelines, and illegal discharges) have contaminated groundwater with localized plumes of petroleum fuels, solvents, and other hazardous substances. In general, these plumes are limited to shallow groundwater. However, as the aquifers and confining layers in these alluvial basins are typically interfingered, the quality of groundwater in the deeper production aquifers can be threatened by the migration of pollutants from the upper aquifers. Overall, the groundwater in the CBWCB continues to be of high quality, suitable for potable and non-potable uses, and continues to meet regulatory requirements.

II. OVERVIEW OF CENTRAL BASIN AND WEST COAST BASIN

Two of the most important groundwater basins in Southern California are the Central Basin and the West Coast Basin (CBWCB), which are located in the southern portion of Los Angeles County (refer to Figure 1 above). Groundwater in the CBWCB meets approximately a third of the overall water supply needs of nearly 4 million residents and businesses in the 43 cities overlying the basins. **Figure 3** below depicts the cities in the CBWCB.

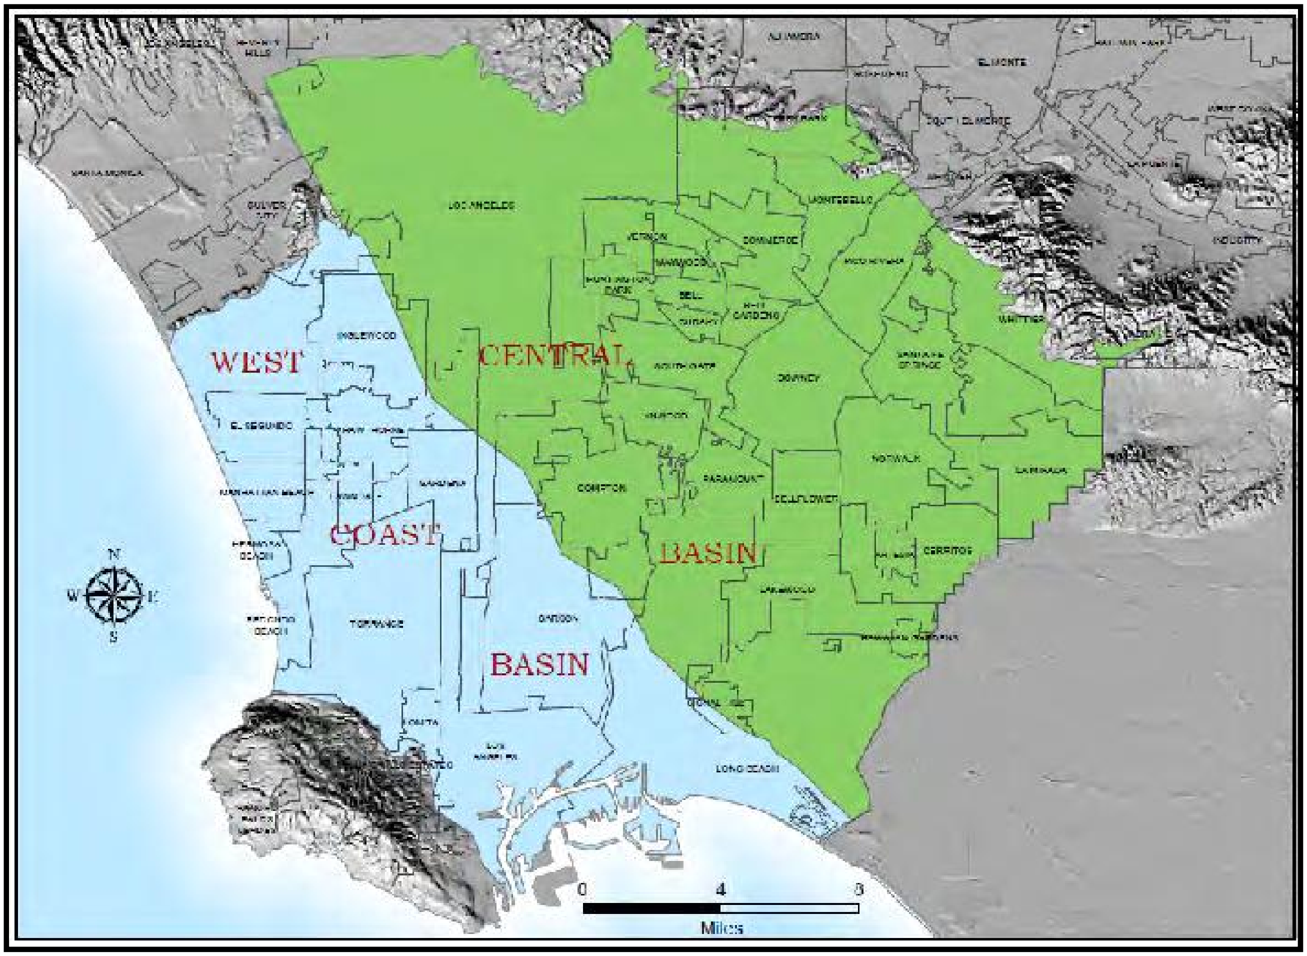

FIGURE 3
Cities in the CBWCB

Source: WRD

1. PHYSIOGRAPHIC DESCRIPTION

The Central Basin and the West Coast Basin (CBWCB) are two groundwater basins in the Coastal Plain of Los Angeles County, California (refer to Figure 1). The major land forms of the Coastal Plain consist of bordering highlands and foothills, older plains and hills, younger alluvial plains, the rivers which drain the area, and the offshore topography. Refer to **Figure 2** below for the physiographic features of the Los Angeles region.

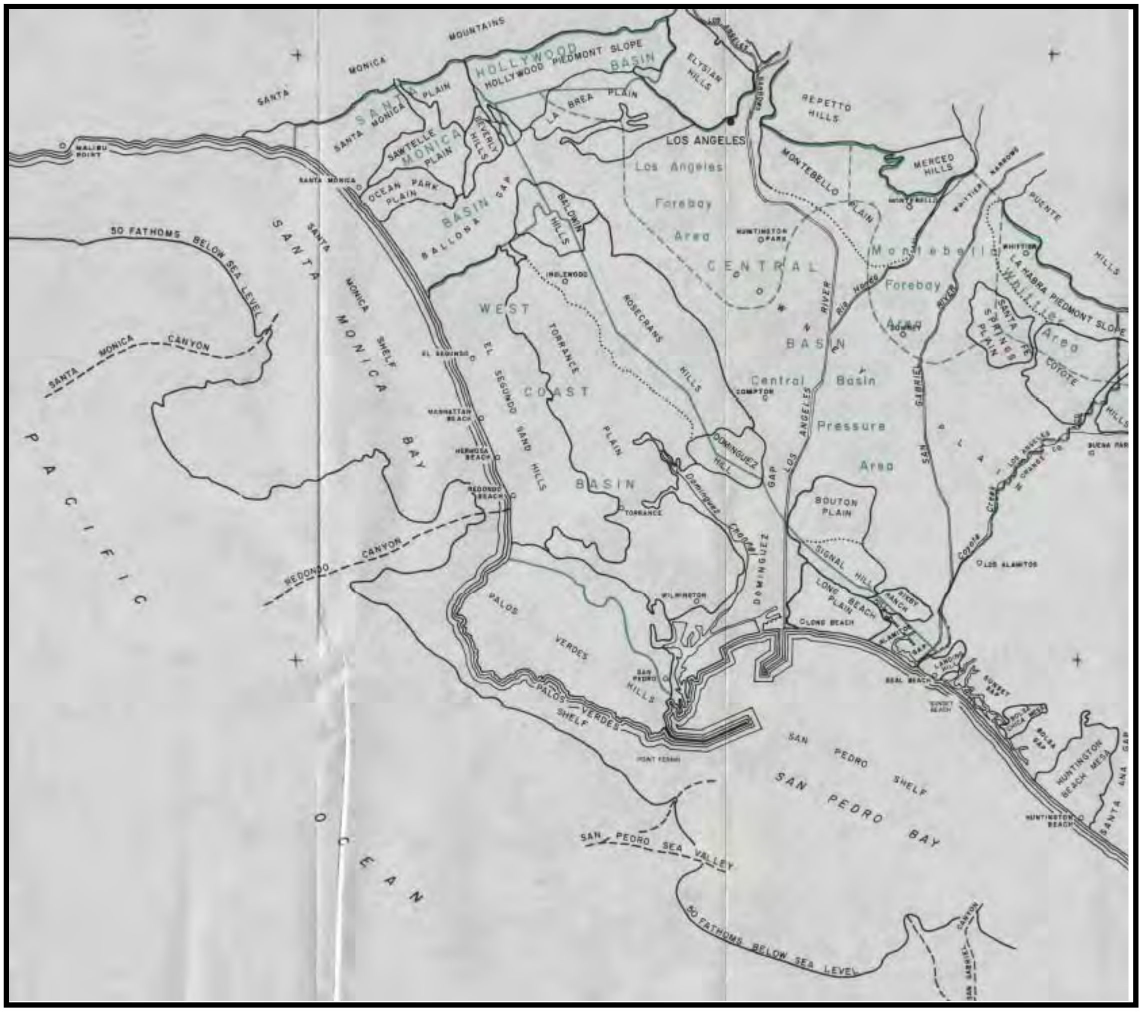

FIGURE 2
Physiographic Features of the Los Angeles Region

Source: DWR

2. GROUNDWATER BASIN BOUNDARIES

The Central Basin covers approximately 270 square miles and is bounded on the north by the Hollywood Basin and the Elysian, Repetto, Merced, and Puente Hills, to the east by the Los Angeles County/Orange County line, and to the south and west by the Newport-Inglewood Uplift, a series of discontinuous faults and folds that form a prominent line of northwest-trending hills including the Baldwin Hills, Dominguez Hills, and Signal Hill.

The West Coast Basin covers approximately 140 square miles and is bounded on the north by the Baldwin Hills and the Ballona Escarpment (a bluff just south of Ballona Creek), on the east by the Newport-Inglewood Uplift, to the south by San Pedro Bay and the Palos Verdes Hills, and to the west by Santa Monica Bay.

3. GEOLOGY

The CBWCB lies within the western portion of the Transverse Ranges Geomorphic Province. The water-bearing deposits in the CBWCB tapped for beneficial use are mostly comprised of Quaternary-age sediments (less than 1.8 million years old) of gravel, sand, silt, and clay that were deposited in layers from the erosion of nearby hills and mountains whose sediments were carried by wind and water flow, and from historic beaches and shallow ocean floors that covered the area at various times in the past. Underlying these Quaternary sediments are basement rocks of the Pliocene Pico Formation that generally do not provide sufficient quantities of groundwater to wells for economic development. Dividing the CBWCB is the Newport-Inglewood Uplift.

4. HYDROGEOLOGY/HYDROLOGY

As depicted in Figure 2, the Central Basin is divided into four sections: the Los Angeles Forebay, the Montebello Forebay, the Whittier Area, and the Pressure Area (DWR, 1961). The two forebays represent areas of unconfined (water table) aquifers that allow percolation of surface water down into the deeper production aquifers to replenish the rest of the basin. The Whittier Area and Pressure Area are confined aquifer systems that receive relatively minimal recharge from surface water, but are replenished from the upgradient forebay areas, mountainfront recharge, or other groundwater basins.

In the West Coast Basin, aquifers are generally confined and receive the majority of their natural replenishment from adjacent groundwater basins or from the Pacific Ocean (seawater intrusion). Both the Newport-Inglewood Uplift and the Charnock Fault (in the West Coast Basin) are partial barriers to groundwater flow, causing differences in water levels on opposite sides of each fault system. Groundwater flows between the Central Basin and the West Coast Basin based on the groundwater elevations on either side of the Newport-Inglewood Uplift. Most of the groundwater in the CBWCB remains at an elevation below sea level due to historic overpumping, so the importance of maintaining the seawater barrier wells to keep out the intruding saltwater is of vital importance.

5. AQUIFERS

Groundwater occurs in the pore spaces of the sediments in the CBWCB. Where these sediments are thick and transmissive enough to supply sufficient quantities of water to wells for beneficial use, they are termed "aquifers." In contrast, the name "aquitard" is given to the less permeable silt and clay layers that separate the aquifers.

The most accepted hydrogeologic description of the basin and the names of water-bearing zones were provided in California Department of Water Resources' *Bulletin No. 104: Planned Utilization of the Ground Water Basins of the Coastal Plain of Los Angeles County, Appendix A – Ground Water Geology* (DWR, 1961). WRD generally follows the naming conventions of this report (Bulletin 104), redefining certain aspects when new data become available. The major aquifers (i.e. discrete groundwater zones) and aquitards, from shallowest to deepest, in the CBWCB are identified in **Table 1** below.

TABLE 1
AQUIFER SYSTEMS IN THE CENTRAL BASIN AND WEST COAST BASIN

Age	Formation	Aquifer/Aquitard
Recent (Holocene)	Active Dune Sand	Semi-Perched Aquifer
	Alluvium	Bellflower Aquitard (mostly absent in the Montebello Forebay)
		Gaspur Aquifer
Upper Pleistocene	Older Dune Sand	Semi-Perched
	Lakewood	Exposition & Artesia Aquifers
		Gardena and Gage Aquifers (also referred to as 200-Foot Sand Aquifer)
Lower Pleistocene	Upper San Pedro	Hollydale Aquifer
		Jefferson Aquifer
		Lynwood Aquifer (also referred to as 400-Foot Gravel Aquifer)
		Silverado Aquifer
	Lower San Pedro	Sunnyside Aquifer
Upper Pliocene	Pico	

Aquifer depths can reach over 2,000 feet in the Central Basin and 1,500 feet in the West Coast Basin and are separated by aquitards. The main potable production aquifers are the deeper Lynwood, Silverado, and Sunnyside Aquifers. The shallower aquifers, including the Gage and Gardena Aquifers locally produce potable water. Also shown on the geologic sections are the aquitards separating aquifers. Many references are made to the Silverado Aquifer which is typically the main producing aquifer in the CBWCB. Substantial production can come from the Lynwood and Sunnyside Aquifers as well.

6. HYDROLOGIC AREAS TRIBUTARY TO THE GROUNDWATER BASINS

The CBWCB is located within the Los Angeles-San Gabriel Hydrologic Unit, which is a drainage area that totals approximately 1,608 square miles. Within the Los Angeles–San Gabriel Hydrologic Unit, the CBWCB is located in the Coastal Plain Hydrologic Area and the Palos Verdes, West Coast, and Central Hydrologic Subareas. Land use within these hydrologic subareas is predominantly residential, commercial, and industrial, and thus, the vast majority of the area is covered with semi-permeable or non-permeable material (e.g., paved). The Los Angeles River and the San Gabriel River, which are the major drainage systems in the Coastal

Plain Hydrologic Area, drain the coastal watersheds of the Transverse Ranges. These surface waters also provide natural recharge to large reserves of groundwater that exist in aquifers underlying the CBWCB. Groundwater in the CBWCB is also artificially recharged through the operation of the Montebello Forebay spreading grounds, the seawater intrusion barriers along the coast (West Coast Basin Barrier, Dominguez Gap Barrier, and Alamitos Barrier), and other recharge areas.

7. CLIMATE

The CBWCB is characterized by a Mediterranean climate, i.e. warm to hot, dry summers and mild to cool, wet winters, with relatively modest transitions in temperature. Most of the rainfall occurs during winter and spring (between December and March). Rainfall data will be provided in the final CBWCB SNMP.

8. LAND COVER AND LAND USE

The CBWCB covers approximately 420 square miles in southern Los Angeles County and consists of 43 cities with a population of nearly 4 million residents. Most of the CBWCB is developed as urban areas with buildings and paved surfaces. Predominant land uses include urban residential, commercial, and industrial. The economy in the CBWCB is primarily industrial, commercial, and service.

9. WATER SOURCES

Water sources in the CBWCB include groundwater, imported water, recycled water, and stormwater. Water is imported into the CBWCB from three major sources: the Sacramento-San Joaquin Delta (northern California), Colorado River, and Owens Valley/Mono Basin (eastern Sierra Nevada Mountains). Recycled water produced by various water reclamation plants in the CBWCB has many uses, including groundwater recharge, urban landscape irrigation, agricultural irrigation, industrial and commercial process water, recreational facilities, and wildlife habitat maintenance.

10. GROUNDWATER BENEFICIAL USES

The major water bodies, including inland surface waters, groundwater, coastal waters, and coastal wetlands, in the CBWCB are designated as having one or more beneficial uses, as defined in the Water Quality Control Plan (Basin Plan) that was developed by the Regional Water Quality Control Board, Los Angeles Region (LARWQCB). These beneficial uses are used by the LARWQCB to establish regulatory thresholds (i.e. water quality objectives) to protect the water supply. The current beneficial uses designated for groundwater in the CBWCB include municipal and domestic supply, agricultural supply, industrial process supply, and industrial service supply.

III. GROUNDWATER WELLS IN THE CBWCB

Prior to 1995, WRD relied heavily upon groundwater monitoring data collected, interpreted, and presented by other entities such as the LACDPW, the DWR, and the private sector for understanding basin conditions. However, these data were collected primarily from production wells, which are typically screened across multiple aquifers to maximize water inflow. The result is a mixing of waters from the different aquifers connected by a single well casing, causing an averaging of water levels and water quality. To more accurately monitor groundwater conditions, WRD established the RGWMP and installed nested groundwater monitoring wells and conducting depth-specific water quality and water level monitoring. The RGWMP changed the focus of groundwater monitoring efforts in the CBWCB to a layered multiple aquifer system with individual zones of groundwater quality and groundwater levels. WRD views each aquifer as a significant component of the groundwater system and recognizes the importance of the interrelationships between water-bearing zones.

As part of the RGWMP, WRD performs extensive collection, analysis, and reporting of groundwater data to refine the hydrogeologic conceptual model of the CBWCB, detect groundwater contamination, evaluate trends in water quality characteristics, and assure compliance with drinking water standards. Thus, the RGWMP establishes baseline regional monitoring as a first step towards detecting any degradation to the quality of the region's groundwater supply.

1. PRODUCTION WELLS

Groundwater production wells are the main source of groundwater extraction and usage in the CBWCB. There are currently over 400 active production wells in the CBWCB (refer to **Figure 4** below). Production wells are typically screened across multiple aquifers to maximize water inflow. In order to meet drinking water quality and production objectives, drinking water supply wells are typically screened in the deeper production aquifers, such as the Lynwood, Silverado, and Sunnyside Aquifers. Production well names are assigned by the well owner, but every production well in the CBWCB is assigned a 6-digit WRD ID number.

The State Water Resources Control Board (SWRCB) Division of Drinking Water (formerly California Department of Public Health) regulates all public water systems in the State to ensure the delivery of safe drinking water to all Californians. In this capacity, the SWRCB Division of Drinking Water performs field inspections of water systems, issues operating permits, reviews plans and specifications for new water infrastructure facilities, takes enforcement actions for non-compliance with laws and regulatory limits, reviews water quality monitoring results, and supports and promotes water system security. The SWRCB Division of Drinking Water also establishes the monitoring requirements for drinking water wells and all the data collected must be reported to the SWRCB Division of Drinking Water by the well owner.

Production wells that supply drinking water are regulated under Title 22 of the California Code of Regulations. Title 22 also establishes the regulatory limits, including Maximum Contaminant Levels (MCLs), Secondary Maximum Contaminant Levels (SMCLs), and Action Levels (ALs) for certain chemicals, including volatile organic compounds (VOCs), non-volatile synthetic organic compounds (SOCs), inorganic chemicals, radionuclides, disinfection byproducts, and other general physical constituents. **Appendix A** provides the current regulatory limits established by the SWRCB Division of Drinking Water for chemicals in drinking water. An MCL is the highest level of a contaminant that is allowed in drinking water and is protective of human health. MCLs not only reflect the chemicals' health risks but also factors such as their detectability and treatability, as well as the cost of treatment. SMCLs are water quality standards established to manage drinking water for aesthetic considerations, such as taste, color, and odor. An AL is defined in Title 22 as a concentration of a contaminant which, if exceeded, triggers treatment or other requirements that a water system must follow.

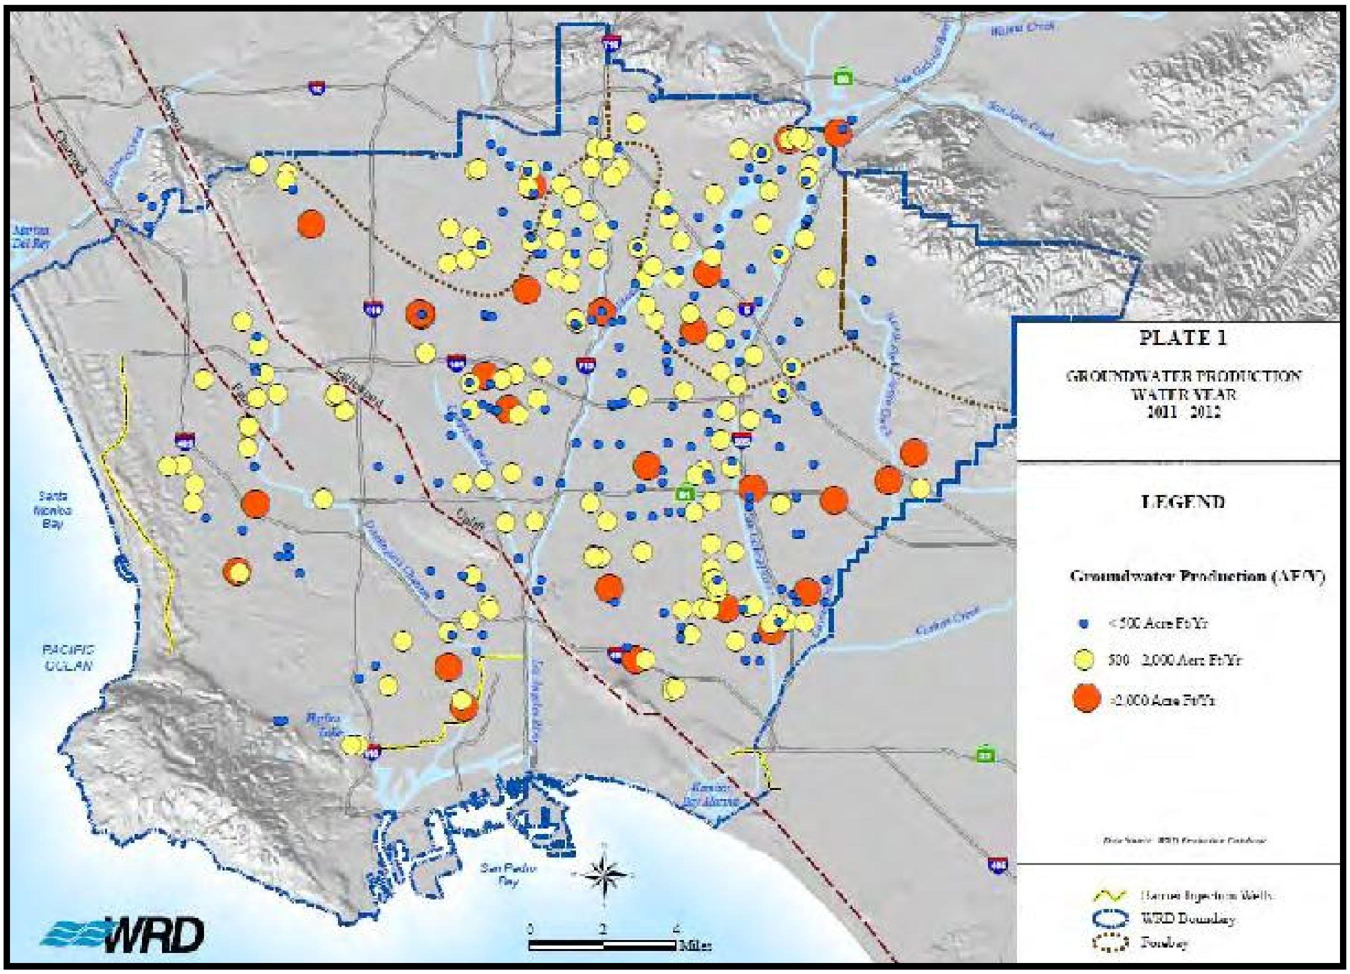

FIGURE 4
Groundwater Production Wells in the CBWCB (Water Year 2011 – 2012)

Source: WRD

2. NESTED MONITORING WELLS

The RGWMP currently consists of a network of over 300 nested monitoring wells located at 55 locations throughout the CBWCB. **Table 2** below lists the nested monitoring wells and their well construction details. WRD plans to install additional monitoring wells as needed when significant data gaps are recognized to enhance its monitoring well network and improve the understanding of the complex underground aquifer network.

A. Well Locations

Well locations are selected to provide a reasonably spaced aerial coverage and to address needs for local water quality and water level information to assess groundwater conditions and refine geologic conceptual and computer models. Additional considerations include proximity to production wells, recharge areas, and other areas of concern. **Figure 5** below depicts the locations of the existing nested monitoring wells as of April 2014.

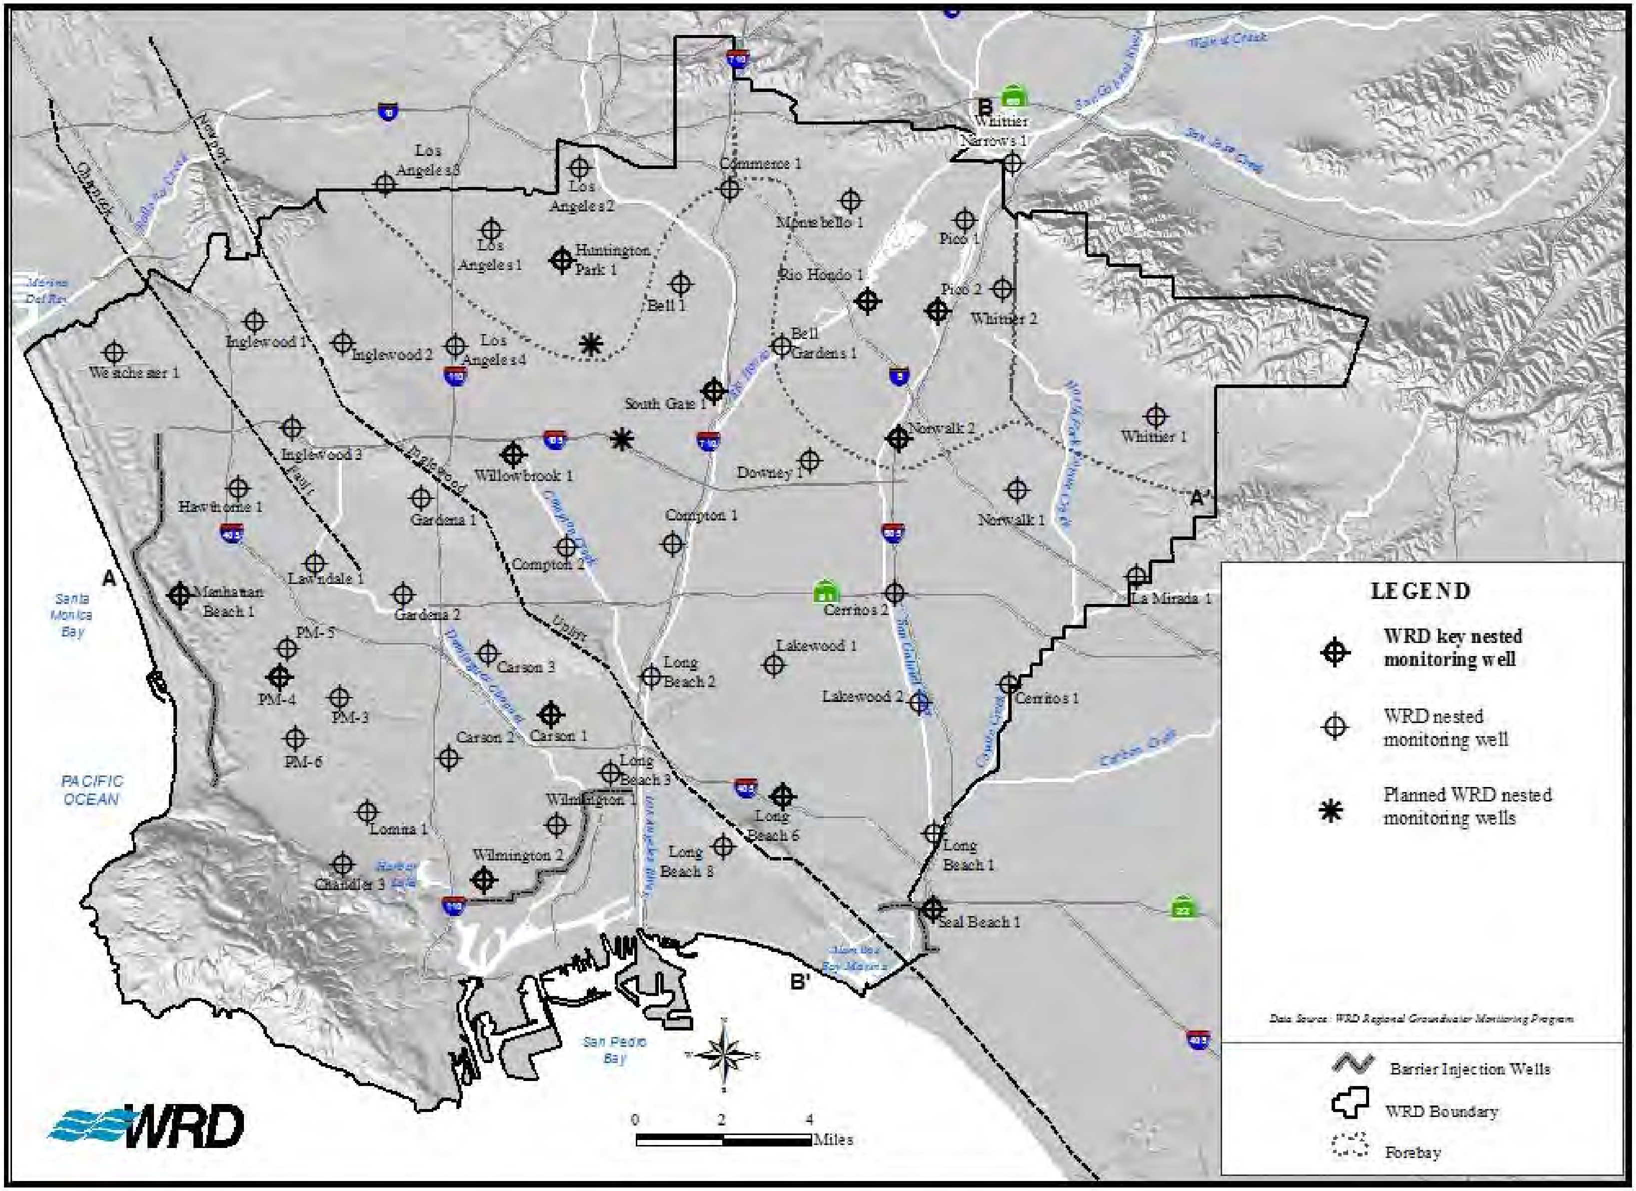

FIGURE 5
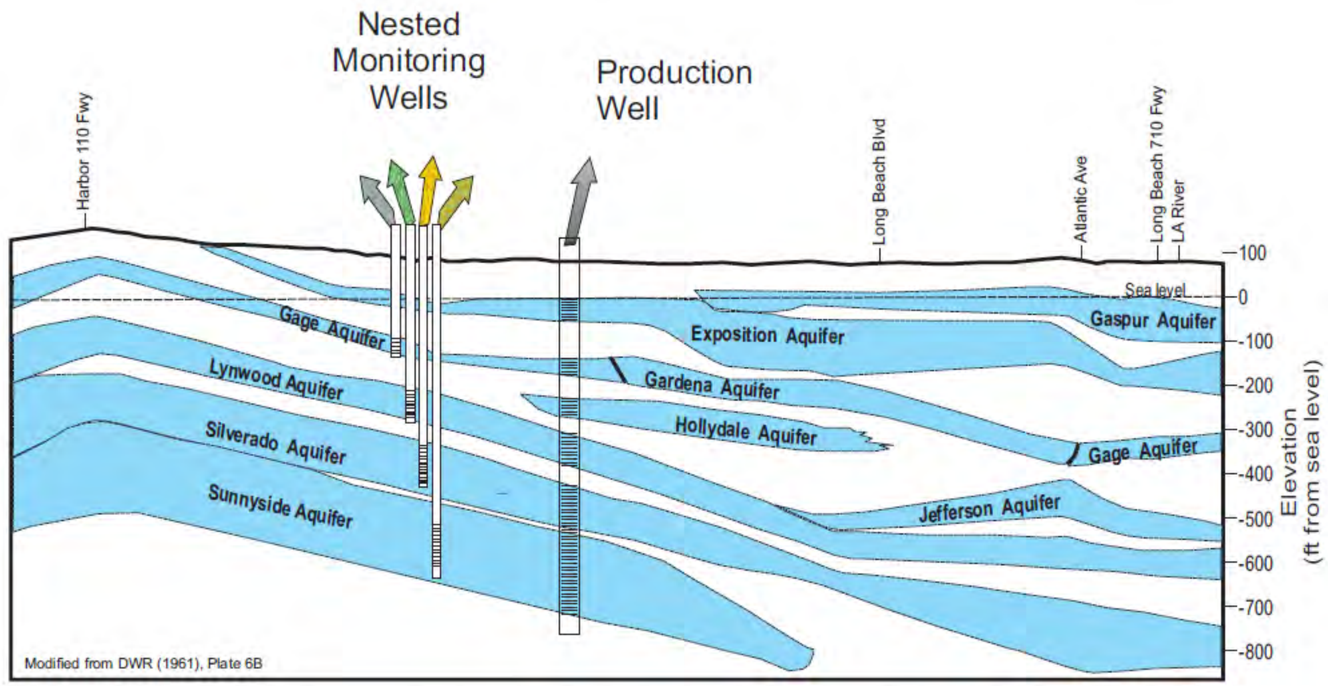
WRD's Nested Groundwater Monitoring Well Locations in the CBWCB
(as of April 2014)

Source: WRD

B. Well Construction

Depth-specific (nested) monitoring wells that tap discrete aquifer zones are necessary in order to obtain more accurate data for specific aquifers from which to infer localized water level and water quality conditions. **Figure 6** below illustrates the capabilities of nested monitoring wells to assess individual aquifers compared to typical production wells.



Production wells are typically perforated across multiple aquifers producing an average water quality. Nested monitoring wells are screened in a portion of a specific aquifer, providing water quality and water level information for the specific zone.

Nested Wells vs. Production Wells for Aquifer-Specific Data

Source: WRD

At each nested well location, a borehole is drilled through the aquifer system and into the Pico Formation to depths that typically range between 1,500 and 2,000 feet below ground surface, depending on the specific geohydrologic conditions of each site. The boring is advanced by a California-licensed drilling company using direct mud rotary drilling techniques. Generally, the nested wells are constructed by the USGS in cooperation with WRD.

The borehole is logged from soil cuttings by a USGS geologist. Standard geophysical logs of all boreholes are run and at selected well sites, advanced suites of borehole logs are collected which include porosity, permeability, and structural information. Once the well is constructed, a comprehensive well construction diagram is completed and all records are filed and maintained by WRD.

Each well nest generally consists of four to six 2-inch Schedule 80 polyvinyl (PVC) monitoring wells installed to different total depths within the same borehole. This allows for monitoring of groundwater levels, water quality, and hydraulic properties for different aquifers at the same location. Nested well screens are typically 20 feet long and consists of 0.020-inch factory-slotted PVC. The well screen depths are selected based on depths where permeable layers (aquifers) are identified using the geophysical logs, lithology (from soil cuttings), logs and hydrographs from existing wells nearby, and existing regional groundwater models.

Well construction materials are placed in the borehole using a tremie pipe. A filter pack of sand typically extends from 20 feet below to 20 feet above each nested well screen. Bentonite grout is placed between the filter packs of the nested wells and as an annular seal to ground surface. Depending on the well location, the wells are completed with either a flush-mounted well vault or a stove pipe monument. The well vaults and monuments are secured with pad lock mechanisms.

Once the wells are constructed, the latitude, longitude, top of casing elevation, and ground surface elevation of each nested well is determined by a California-licensed land surveyor or by Global Positioning System (GPS) technology. These records are filed and maintained by WRD, as further discussed in Section VI Data Management and Access.

C. Well Development

Monitoring wells are thoroughly developed by air lifting and pumping until water quality parameters (pH, electrical conductivity, temperature, and turbidity) indicate that the purged water has reached equilibrium.

D. Well Names and Aquifer Designations

Nested monitoring wells are named based on their location, i.e. the name of the city in which the well is located or other geograghic feature, and are generally followed by a sequence number based on the number of nested well locations that already exist within the area. Zone numbers are assigned consecutively for each nested well, beginning at the deepest screen upward to the shallowest at each well location. A 5-digit WRD ID number is also assigned to each nested monitoring well.

Once the wells are constructed, all available information is used by WRD to assign the aquifer names and stratigraphic unit names to each of the screened zones. Information can include the lithologic log, geophysical logs, logs from existing wells nearby, water quality and water level data, regional groundwater models, and the California Department of Water Resources' *Bulletin No. 104: Planned Utilization of the Ground Water Basins of the Coastal Plain of Los Angeles County, Appendix A – Ground Water Geology* (DWR, 1961).

IV. GROUNDWATER QUALITY MONITORNG

Groundwater samples are collected by WRD from the nested monitoring wells on a bi-annual basis, i.e. Spring and Fall of each year. Annually, as part of the RGWMP, WRD collects nearly 500 groundwater samples from its monitoring well network and analyzes them for over 100 water quality constituents to produce nearly 60,000 individual data points to help track the water quality in the basins. By analyzing and reviewing the results on a regular basis, any new or growing water quality concerns can be identified and managed effectively. The results of this monitoring and analysis include data tables, water quality maps, and graphs of trends which are presented in the annual RGWMRs.

1. NESTED MONITORING WELL PURGING AND SAMPLING

Nested monitoring wells are purged and sampled by WRD using submersible centrifugal sampling pumps (Grundfos Rediflo2) or pneumatic piston pumps (Bennett) that are permanently installed in the wells. Generally, a minimum of three casing volumes of water are pumped from the wells and samples are collected when field instruments indicate that water quality parameters (pH, ORP, specific conductance, and temperature) have stabilized and turbidity measurements are below 5 NTUs. Other industry-accepted methods may be used to sample the wells due to challenging local conditions or to evaluate new sampling technologies.

All groundwater samples are collected in laboratory supplied pre-labeled containers and include prescribed preservatives. Groundwater samples are placed in coolers with ice packs and transported to the State-certified laboratory (currently, Eurofins Eaton Analytical of Monrovia, California) following standard chain-of-custody procedures.

2. WATER QUALITY PARAMETERS

Table 3 below provides a list of the water quality parameters that are analyzed for groundwater samples collected from each nested monitoring well. Other constituents may occasionally be added to the list for certain wells or for special studies.

TABLE 3
WATER QUALITY PARAMETERS OF THE RGWMP
(As of April 2014)

Constituent	Chemical Storet No.	Laboratory Analytical Method
1,1,1,2-Tetrachloroethane	77562	EPA 524.2

3. QA/QC PROCEDURES

Quality assurance/quality control (QA/QC) of the RGWMP includes collection of field blanks and blind duplicates. Unusual analytical results are noted and compared to historical values/trends and if the result appears to be an outlier or anomaly, the result is flagged in the WRD database.

Laboratory QA/QC samples collected include method blanks, laboratory control standards (LCS), matrix spike/matrix spike duplicates (MS/MSDs), and surrogate spikes. Laboratory reports, which include sampling and QA/QC results, are posted on the password-protected laboratory website. QA/QC documentation for Eurofins Eaton Analytical is provided in **Appendix B**.

V. GROUNDWATER LEVEL MONITORING

Groundwater levels are an indication of the amount of groundwater in the basins. They reveal areas of recharge and discharge from the basins, suggest which way the groundwater is moving so that recharge water or contaminants can be tracked, are used to determine when additional replenishment water is required, and are used to calculate storage changes. Groundwater levels can also be used to demonstrate possible source areas for seawater intrusion or show the effectiveness of seawater barrier wells.

Groundwater levels in the CBWCB have been monitored and recorded since the early 1900s. Water level data going back to the 1930s and 1940s in the Montebello Forebay, Los Angeles Forebay, Central Basin Pressure Area, and West Coast Basin are presented in hydrographs, which are published in WRD's annual Engineering Survey and Report (ESR). The hydrographs illustrate the general history of groundwater conditions in the CBWCB: 1) Steep water level declines occurred in the 1930s through 1950s as a result of excessive pumping (overdraft); 2) In the mid-1950s to early 1960s, there was a sharp reversal in this downward trend due to initiation of groundwater management policies, water levels increased through the 1970s and 1980s in response to reduced pumping, artificial replenishment by WRD, and seawater barrier construction and injection; and 3) Over the past 10 to 15, years water levels have remained relatively stable as replenishment has been in closer balance to withdrawals.

WRD tracks groundwater levels throughout the year by measuring the depth to water in nested monitoring wells and production wells located throughout the CBWCB. Groundwater levels in the nested monitoring wells are manually measured by WRD at least four times per year using electronic depth-to-water indicators with marked intervals of 0.01 foot.

Additionally, in order to capture the daily and seasonal variations in water levels, WRD typically installs automatic data-logging equipment (pressure transducers and data-loggers) in nested monitoring wells to collect water levels every six hours. WRD also obtains water level data from cooperating entities such as the pumpers, DWR, and LACDPW, who collect water levels from their wells. These data are entered into WRD's database for archiving and analysis, as discussed in Section VI Data Management and Access.

Using data collected from the RGWMP, WRD tracks the changes in water levels over time in specific aquifers by preparing hydrographs for each of the nested monitoring wells. Hydrographs reveal the seasonal fluctuations of water levels caused by variations in natural and artificial recharge, and the effects of pumping and other basin discharge. Hydrographs for key nested monitoring wells are presented in the WRD's annual RGWMRs.

VI. DATA MANAGEMENT AND ACCESS

All information collected from the RGWMP is stored and managed in WRD's Database Management System (DBMS) and Geographic Information System (GIS). The GIS links spatially-related information (e.g., well locations, geologic features, cultural features, contaminated sites) to data regarding well production, water quality, water levels, and replenishment amounts. WRD uses industry standard ArcGIS® software for data analysis and preparation of spatially-related information (maps and graphics tied to data). WRD utilizes GPS technology to survey the locations of production wells, nested monitoring wells, and other geographic features for use in the GIS database.

Analytical reports from the nested monitoring well sampling events are e-mailed to WRD from the laboratory in electronic data deliverable (EDD) format and can also be downloaded from the password-protected laboratory website (www.eatonanalytical.com). EDD files are directly uploaded into the DBMS. In addition to nested well water quality data, the DBMS stores regulatory limits for various chemicals, water quality data supplied by the SWRCB Division of Drinking Water for drinking water wells, groundwater level monitoring data, well construction data, and other important information related to groundwater replenishment and production.

In early 2003, WRD implemented the internet-based GIS and Interactive Well Search Tool, which was made available to the public for access to groundwater data, including water quality data of nested monitoring wells and drinking water wells, groundwater levels, well locations, well construction details, and groundwater production. Well information can be obtained through an interactive map or text searches and the results can be displayed in both tabular and graphical formats. This online tool can be accessed through the WRD website (http://gis.wrd.org/wrdmap/login.asp) once the user sets up a username and password.

WRD is constantly updating the DBMS and GIS with new data acquired from the RGWMP and newly-acquired archived data provided by pumpers and other agencies. The GIS is a primary tool for WRD and other water-related agencies to more accurately track current and past use of groundwater, track groundwater quality, and project future water demands, thus allowing improved management of the groundwater basins.

On November 4, 2009 the State Legislature amended the Water Code with SBx7-6, mandating a statewide groundwater elevation monitoring program to track seasonal and long-term trends in California's groundwater basins. In accordance with this amendment DWR developed the California Statewide Groundwater Elevation Monitoring (CASGEM) program. In October 2011, WRD was designated the agency responsible for collecting and reporting CBWCB groundwater level data to CASGEM. Through the RGWMP, WRD continues to provide the data to the CASGEM program by collecting groundwater level data and tracking seasonal and long-term trends in the CBWCB.

VII. ANNUAL REPORTS

WRD has been monitoring groundwater quality in the CBWCB for over 50 years. An *Annual Report on the Results of Water Quality Monitoring (Annual Report)* was published by WRD each year for WYs 1972-73 through 1994-95, and was based on a basin-wide monitoring program outlined in the *Report on Program of Water Quality Monitoring* (Bookman-Edmonston Engineering, Inc., January 1973). The latter report recommended a substantial expansion of the then-existing program, particularly the development of a detailed and intensive program of monitoring the quality of groundwater in the Montebello Forebay. In response, WRD implemented the current RGWMP to serve as an expanded, more representative basin-wide monitoring program for the CBWCB. Beginning WY 1995-96, RGWMRs were published in lieu of the previous *Annual Reports*.

WRD's annual RGWMRs present the most comprehensive information to date regarding the growing network of aquifer-specific monitoring wells and in-depth water quality analyses. Each RGWMR presents groundwater data collected during the previous water year, which runs from October 1 through September 30 of each year. Hard copies of the RGWMRs are mailed to stakeholders within the CBWCB and electronic copies are posted on the WRD website (http://www.wrd.org/engineering/groundwater-engineering-reports.php) for download.

The RGWMRs includes maps and trend graphs to focus on ten key water quality constituents, including total dissolved solids (TDS), iron, manganese, nitrate, chloride, trichloroethylene (TCE), tetrachloroethylene (PCE), arsenic, perchlorate, and hexavalent chromium, to represent overall groundwater quality in the basins. TDS, where elevated, is typically present along with chloride as an indicator of historic seawater intrusion. The most prevalent water quality issue in the CBWCB is manganese, a naturally-occurring contaminant that requires treatment prior to delivery as drinking water. TCE and PCE, volatile organic contaminants that can leak into groundwater from industrial and commercial facilities, have also impacted wells in the CBWCB and are closely monitored. WRD is also currently investigating perchlorate, hexavalent chromium, and other emerging contaminants of concern.

WRD will continue to use the data generated by the RGWMP to address current and upcoming issues related to water quality and groundwater replenishment in the CBWCB.

APPENDIX A

Table of Regulatory Limits Established for Chemicals in Drinking Water

MCLs, DLRs, and PHGs for Regulated Drinking Water Contaminants

(Units are in milligrams per liter (mg/L), unless otherwise noted.)

Last Update: July 1, 2014

This table includes:

California's maximum contaminant levels (MCLs)

Detection limits for purposes of reporting (DLRs)

Public health goals (PHGs) from the Office of Environmental Health Hazard Assessment (OEHHA)

Also, PHGs for NDMA and 1,2,3-Trichloropropane (which are not yet regulated) are included at the bottom of this table.

	MCL	DLR	PHG	Date of PHG
Chemicals with MCLs in 22 CCR §64431—Inorganic Chemicals				
Aluminum	1	0.05	0.6	2001
Antimony	0.006	0.006	0.02	1997
Antimony	--	--	0.0007	2009 draft

MCLs, DLRs, and PHGs for Regulated Drinking Water Contaminants				
(Units are in milligrams per liter (mg/L), unless otherwise noted.)				
Last Update: July 1, 2014				
This table includes: California's maximum contaminant levels (MCLs) Detection limits for purposes of reporting (DLRs) Public health goals (PHGs) from the Office of Environmental Health Hazard Assessment (OEHHA) Also, PHGs for NDMA and 1,2,3-Trichloropropane (which are not yet regulated) are included at the bottom of this table.				
	MCL	**DLR**	**PHG**	**Date of PHG**
Chemicals with PHGs established in response to CDPH requests. These are not currently regulated drinking water contaminants.				
N-Nitrosodimethylamine (NDMA)	--	--	0.000003	2006
1,2,3-Trichloropropane	--	--	0.0000007	2009
*OEHHA's review of this chemical during the year indicated (rev20XX) resulted in no change in the PHG.				
**The DLR for Bromate is 0.0010 mg/L for analysis performed using EPA Method 317.0 Revision 2.0, 321.8, or 326.0.				

APPENDIX B

QA/QC Documentation for
Eurofins Eaton Analytical of Monrovia, California

RON CHAPMAN, MD, MPH
Director & State Health Officer

State of California—Health and Human Services Agency

California Department of Public Health

EDMUND G. BROWN JR.
Governor

January 9, 2013

Ed Wilson
Eurofins Eaton Analytical, Inc. (former M.W.H.)
750 Royal Oaks Drive, Suite 100
Monrovia, CA 91016

Dear Ed Wilson: Certificate No. 01114CA

This is to advise you that the laboratory named above has been accredited under National Environmental Laboratory Accreditation Program (NELAP) as an environmental testing laboratory pursuant to the provisions of the Health and Safety Code (HSC), Division 101, Part 1, Chapter 4, Section 100825, *et seq.*

The Fields of Accreditation for which this laboratory has been accredited are enclosed. The certificate shall remain in effect until **January 31, 2014** unless revoked by California Environmental Laboratory Accreditation Program Branch (ELAPB) or withdrawn at your written request. To maintain accreditation, the laboratory shall comply with the National Environmental Laboratory Accreditation Conference (NELAC) Standards and all associated California ELAPB regulations and statutes.

The application for renewal of this certificate must be received before the expiration date of this certificate to remain in force according to the HSC 100847(a).

Please note that your laboratory is required to notify California ELAPB of any major changes in key accreditation criteria within 30 calendar days of the change. This written notification includes, but is not limited to, changes in ownership, location, key personnel, and major instrumentation (HSC 100847(b), (c), (d), and NELAC Standard Section 4.3.2). The certificate must be returned to California ELAPB upon loss of accredited status.

Your continued cooperation with the above requirements is essential for maintaining the high quality of the data produced by environmental laboratories accredited by the State of California.

If you have any questions, please contact Bill Walker at (818) 551-2012.

Sincerely,

Fred Choske for

David Mazzera, Ph.D., Assistant Division Chief
Division of Drinking Water and Environmental Management

Enclosure

NELAP - RECOGNIZED

CALIFORNIA STATE

ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM BRANCH

CERTIFICATE OF NELAP ACCREDITATION

Is hereby granted to

Eurofins Eaton Analytical, Inc. (former M.W.H.)

750 Royal Oaks Drive, Suite 100

Monrovia, CA 91016

Scope of the Certificate is limited to the
"NELAP Fields of Accreditation"
which accompany this Certificate.

Continued accredited status depends on successful
ongoing participation in the program.

This Certificate is granted in accordance with provisions of
Section 100825, et seq. of the Health and Safety Code.

Certificate No.: **01114CA**

Expiration Date: **1/31/2014**

Effective Date: **2/1/2013**

Richmond, California
subject to forfeiture or revocation

David Mazzera, Ph.D., Assistant Division Chief
Division of Drinking Water and Environmental Management

Ed Wilson
Eurofins Eaton Analytical, Inc.
750 Royal Oaks Drive, Suite 100
Monrovia, CA 91016

Dear Ed Wilson: Certificate No. 2813

This is to advise you that the laboratory named above has been certified as an environmental testing laboratory pursuant to the provisions of the Health and Safety Code (HSC), Division 101, Part 1, Chapter 4, Section 100825, *et seq.*

The Fields of Testing for which this laboratory has been certified are indicated on the enclosed "Fields of Testing." The certificate shall remain in effect until **January 31, 2015** unless it is revoked. This certificate is subject to an annual fee as prescribed by HSC 100860.1(a).

The application for renewal of this certificate must be received before the expiration date of this certificate to remain in force according to the HSC 100845(a).

Any changes in laboratory location or structural alterations, which may affect adversely the quality of analysis in the Fields of Testing for which this laboratory has been granted a certificate, require prior notification. Notification is also required for changes in ownership or laboratory director within 30 days after the change (HSC, Section 100845(b) and (d)).

Your continued cooperation with the above requirements is essential for maintaining the high quality of the data produced by environmental laboratories certified by the State of California.

If you have any questions, please contact Rosalinda Lomboy at (818) 551-2014.

Sincerely,

David Mazzera, Ph.D., Assistant Division Chief
Division of Drinking Water and Environmental Management

ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM BRANCH

CERTIFICATE OF ENVIRONMENTAL ACCREDITATION

Is hereby granted to

Eurofins Eaton Analytical, Inc.

750 Royal Oaks Drive, Suite 100

Monrovia, CA 91016

Scope of the certificate is limited to the
"Fields of Testing"
which accompany this Certificate.

Continued accredited status depends on successful completion of on-site, proficiency testing studies, and payment of applicable fees.

This Certificate is granted in accordance with provisions of Section 100825, et seq. of the Health and Safety Code.

Certificate No.: **2813**

Expiration Date: **1/31/2015**

Effective Date: **2/1/2013**

Richmond, California
subject to forfeiture or revocation

109.020	018	Zinc	EPA 200.8
109.020	020	Gold	EPA 200.8
109.020	021	Iron	EPA 200.8
109.020	022	Tin	EPA 200.8
109.020	023	Titanium	EPA 200.8
109.104	001	Chromium (VI)	EPA 218.6
109.190	001	Mercury	EPA 245.1
109.824	001	Iron	SM3500-Fe B (20th)
109.825	001	Iron	SM3500-Fe D (18th/19th)

Field of Testing: 110 - Volatile Organic Chemistry of Wastewater

110.040	040	Halogenated Hydrocarbons	EPA 624
110.040	041	Aromatic Compounds	EPA 624
110.040	042	Oxygenates	EPA 624
110.040	043	Other Volatile Organics	EPA 624

Field of Testing: 111 - Semi-volatile Organic Chemistry of Wastewater

111.101	032	Polynuclear Aromatic Hydrocarbons	EPA 625
111.101	033	Adipates	EPA 625

111.101	034	Phthalates	EPA 625
111.101	036	Other Extractables	EPA 625
111.170	030	Organochlorine Pesticides	EPA 608
111.170	031	PCBs	EPA 608
111.272	001	Oil and Grease	SM5520B (20th)
111.273	001	Oil and Grease	EPA 1664A

NELAP - RECOGNIZED

CALIFORNIA STATE

ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM BRANCH

CERTIFICATE OF NELAP ACCREDITATION

Is hereby granted to

APPL, Inc. (Agriculture & Priority Pollutants Laboratories, Inc.)

908 North Temperance Avenue

Clovis, CA 93611

Scope of the Certificate is limited to the
"NELAP Fields of Accreditation"
which accompany this Certificate.

Continued accredited status depends on successful
ongoing participation in the program.

This Certificate is granted in accordance with provisions of
Section 100825, et seq. of the Health and Safety Code.

Certificate No.: **05233CA**

Expiration Date: **1/31/2014**

Effective Date: **2/1/2013**

Richmond, California
subject to forfeiture or revocation

David Mazzera, Ph.D., Assistant Division Chief
Division of Drinking Water and Environmental Management

NELAP - RECOGNIZED

CALIFORNIA STATE

ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM BRANCH

CERTIFICATE OF NELAP ACCREDITATION

Is hereby granted to

APPL, Inc. (Agriculture & Priority Pollutants Laboratories, Inc.)

908 North Temperance Avenue

Clovis, CA 93611

Scope of the Certificate is limited to the
"NELAP Fields of Accreditation"
which accompany this Certificate.

Continued accredited status depends on successful
ongoing participation in the program.

This Certificate is granted in accordance with provisions of
Section 100825, et seq. of the Health and Safety Code.

Certificate No.: **05233CA**

Expiration Date: **1/31/2013**

Effective Date: **2/1/2012**

Richmond, California
subject to forfeiture or revocation

George C. Kulasingam, Ph.D., Chief
Environmental Laboratory Accreditation Program Branch

EDMUND G. BROWN JR.
Governor

July 6, 2012

Tu Nisamaneepong, Ph.D.
EMAX Laboratories, Inc.
1835 West 205th Street
Torrance, CA 90501

Dear Tu Nisamaneepong, Ph.D.: Certificate No. 02116CA

This is to advise you that the laboratory named above has been accredited under National Environmental Laboratory Accreditation Program (NELAP) as an environmental testing laboratory pursuant to the provisions of the Health and Safety Code (HSC), Division 101, Part 1, Chapter 4, Section 100825, *et seq.*

The Fields of Accreditation for which this laboratory has been accredited are enclosed. The certificate shall remain in effect until **August 31, 2013** unless revoked by California Environmental Laboratory Accreditation Program Branch (ELAPB) or withdrawn at your written request. To maintain accreditation, the laboratory shall comply with the National Environmental Laboratory Accreditation Conference (NELAC) Standards and all associated California ELAPB regulations and statutes.

The application for renewal of this certificate must be received before the expiration date of this certificate to remain in force according to the HSC 100847(a).

Please note that your laboratory is required to notify California ELAPB of any major changes in key accreditation criteria within 30 calendar days of the change. This written notification includes, but is not limited to, changes in ownership, location, key personnel, and major instrumentation (HSC 100847(b), (c), (d), and NELAC Standard Section 4.3.2). The certificate must be returned to California ELAPB upon loss of accredited status.

Your continued cooperation with the above requirements is essential for maintaining the high quality of the data produced by environmental laboratories accredited by the State of California.

If you have any questions, please contact at .

Sincerely,

David Mazzera, Ph.D., Assistant Division Chief
Division of Drinking Water and Environmental Management

NELAP - RECOGNIZED

CALIFORNIA STATE

ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM BRANCH

CERTIFICATE OF NELAP ACCREDITATION

is hereby granted to

EMAX Laboratories, Inc.

1835 West 205th Street

Torrance, CA 90501

Scope of the Certificate is limited to the
"NELAP Fields of Accreditation"
which accompany this Certificate.

Continued accredited status depends on successful
ongoing participation in the program.

This Certificate is granted in accordance with provisions of
Section 100825, et seq. of the Health and Safety Code.

Certificate No.: **02116CA**

Expiration Date: **8/31/2013**

Effective Date: **9/1/2012**

Richmond, California
subject to forfeiture or revocation

David Mazzera, Ph.D., Assistant Division Chief
Division of Drinking Water and Environmental Management

NELAP - RECOGNIZED

CALIFORNIA STATE

ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM BRANCH

CERTIFICATE OF NELAP ACCREDITATION

Is hereby granted to

EMAX Laboratories, Inc.

1835 West 205th Street

Torrance, CA 90501

Scope of the Certificate is limited to the
"NELAP Fields of Accreditation"
which accompany this Certificate.

Continued accredited status depends on successful
ongoing participation in the program.

This Certificate is granted in accordance with provisions of
Section 100825, et seq. of the Health and Safety Code.

Certificate No.: **02116CA**

Expiration Date: **8/31/2014**

Effective Date: **9/1/2013**

Richmond, California
subject to forfeiture or revocation

David Mazzera, Ph.D., Assistant Division Chief
Division of Drinking Water and Environmental Management

Curtis Desilets
Enviro-Chem, Inc.
1214 East Lexington Avenue
Pomona, CA 91766

Dear Curtis Desilets: Certificate No. 1555

This is to advise you that the laboratory named above continues to be certified as an environmental testing laboratory pursuant to the provisions of the Health and Safety Code (HSC), Division 101, Part 1, Chapter 4, Section 100825, et seq. Certification for all currently certified Fields of Testing that the laboratory has applied for renewal shall remain in effect until **06/30/2013** unless it is revoked.

Please note that the renewal application for certification is subject to an on-site process, and the continued use of this certificate is contingent upon:

* **successful completion of the on-site process;**
* **acceptable performance in the required proficiency testing (PT) studies;**
* **timely payment of all fees, including an annual fee due before June 30, 2012;**
* **compliance with Environmental Laboratory Accreditation Program Branch (ELAP) statutes (HSC, Section 100825, et seq.) and Regulations (California Code of Regulations (CCR),Title 22, Division 4, Chapter 19).**

An updated certificate of the "Fields of Testing" will be issued to the laboratory upon successful completion of the on-site process.

The application for the renewal of this certificate must be received before the expiration date to remain in force according to the HSC100845(a).

Please note that the laboratory is required to notify ELAP of any major changes in the laboratory such as the transfer of ownership, change of laboratory director, change in location, or structural alterations which may affect adversely the quality of analyses (HSC, Section 100845(b)(d)). Please include the above certificate number in all your correspondence with ELAP.

If you have any questions, please contact ELAP at (510) 620-3155.

Sincerely,

George C. Kulasingam, Ph.D., Chief
Environmental Laboratory Accreditation Program Branch

CALIFORNIA STATE

ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM BRANCH

CERTIFICATE OF ENVIRONMENTAL ACCREDITATION

Is hereby granted to

Enviro-Chem, Inc.

1214 East Lexington Avenue

Pomona, CA 91766

Scope of the certificate is limited to the
"Fields of Testing"
which accompany this Certificate.

Continued accredited status depends on successful completion of on-site, proficiency testing studies, and payment of applicable fees.

This Certificate is granted in accordance with provisions of Section 100825, et seq. of the Health and Safety Code.

Certificate No.: **1555**

Expiration Date: **06/30/2013**

Effective Date: **07/01/2011**

Richmond, California
subject to forfeiture or revocation

CALIFORNIA STATE

ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM BRANCH

CERTIFICATE OF ENVIRONMENTAL LABORATORY ACCREDITATION

Is hereby granted to

Enviro-Chem, Inc.

1214 East Lexington Avenue

Pomona, CA 91766

Scope of the certificate is limited to the
"Fields of Testing"
which accompany this Certificate.

Continued accredited status depends on successful completion of on-site, proficiency testing studies, and payment of applicable fees.

This Certificate is granted in accordance with provisions of Section 100825, et seq. of the Health and Safety Code.

Certificate No.: **1555**

Expiration Date: **06/30/2015**

Effective Date: **07/01/2013**

Richmond, California
subject to forfeiture or revocation

David Mazzera, Ph.D., Assistant Division Chief
Division of Drinking Water and Environmental Management

Curtis B. Desilets
Enviro-Chem, Inc.
1214 East Lexington Avenue
Pomona, CA 91766

Dear Curtis B. Desilets: Certificate No. 1555

This is to advise you that the laboratory named above continues to be certified as an environmental testing laboratory pursuant to the provisions of the Health and Safety Code (HSC), Division 101, Part 1, Chapter 4, Section 100825, et seq. Certification for all currently certified Fields of Testing that the laboratory has applied for renewal shall remain in effect until **06/30/2015** unless it is revoked.

Please note that the renewal application for certification is subject to an on-site process, and the continued use of this certificate is contingent upon:

- **successful completion of the on-site process;**
- **acceptable performance in the required proficiency testing (PT) studies;**
- **timely payment of all fees, including an annual fee due before June 30, 2014;**
- **compliance with Environmental Laboratory Accreditation Program Branch (ELAPB); statutes (HSC, Section 100825, et seq.) and Regulations (California Code of Regulations (CCR),Title 22, Division 4, Chapter 19).**

An updated certificate of the "Fields of Testing" will be issued to the laboratory upon successful completion of the on-site process.

The application for the renewal of this certificate must be received before the expiration date to remain in force according to the HSC100845(a).

Please note that the laboratory is required to notify ELAPB of any major changes in the laboratory such as the transfer of ownership, change of laboratory director, change in location, or structural alterations which may affect adversely the quality of analyses (HSC, Section 100845(b)(d)). Please include the above certificate number in all your correspondence with ELAPB.

If you have any questions, please contact ELAPB at (510) 620-3155.

Sincerely,

Fred Choske for

David Mazzera, Ph.D., Assistant Division Chief
Division of Drinking Water and Environmental Management

NELAP - RECOGNIZED

CALIFORNIA STATE

ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM BRANCH

CERTIFICATE OF NELAP ACCREDITATION

Is hereby granted to

Lancaster Laboratories, Inc.

2425 New Holland Pike

Lancaster, PA 17601-5994

Scope of the Certificate is limited to the
"NELAP Fields of Accreditation"
which accompany this Certificate.

Continued accredited status depends on successful
ongoing participation in the program.

This Certificate is granted in accordance with provisions of
Section 100825, et seq. of the Health and Safety Code.

Certificate No.: **10276CA**

Expiration Date: **7/31/2012**

Effective Date: **8/1/2012**

Richmond, California
subject to forfeiture or revocation

Dear Dennis J. Leeke:

Certificate No. 04222CA

This is to advise you that the laboratory named above has been accredited under National Environmental Laboratory Accreditation Program (NELAP) as an environmental testing laboratory pursuant to the provisions of the Health and Safety Code (HSC), Division 101, Part 1, Chapter 4, Section 100825, *et seq.*

The Fields of Accreditation for which this laboratory has been accredited are enclosed. Recognition of accreditation is subject to maintaining accreditation with the primary Accreditation Body. In addition, the laboratory shall comply with the National Environmental Laboratory Accreditation Conference (NELAC) Standards and all associated California Environmental Laboratory Accreditation Program Branch (ELAPB) regulations and statutes.

Please note that your laboratory is required to notify California ELAPB of any major changes in key accreditation criteria within 30 calendar days of the change. This written notification includes, but is not limited to, changes in ownership, location, key personnel, and major instrumentation (HSC 100847(b), (c), (d), and NELAC Standard Section 4.3.2). The certificate must be returned to California ELAPB upon loss of accredited status.

Your continued cooperation with the above requirements is essential for maintaining the high quality of the data produced by environmental laboratories accredited by the State of California.

If you have any questions, please contact Linda Louie at (510) 620-3155.

Sincerely,

Fred Choate for

David Mazzera, Ph.D., Assistant Division Chief

NELAP - RECOGNIZED

CALIFORNIA STATE

ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM BRANCH

CERTIFICATE OF NELAP ACCREDITATION

Is hereby granted to

Pace Analytical Services, Inc. - Pittsburgh, PA

1638 Roseytown Road, Suites 2, 3, & 4
Greensburg, PA 15601

Scope of the Certificate is limited to the
"NELAP Fields of Accreditation"
which accompany this Certificate.

Continued accredited status depends on successful
ongoing participation in the program.

This Certificate is granted in accordance with provisions of
Section 100825, et seq. of the Health and Safety Code.

Certificate No.: **04222CA**

Expiration Date: **1/31/2015**

Effective Date: **2/1/2014**

Richmond, California
subject to forfeiture or revocation

RON CHAPMAN, MD, MPH
Director & State Health Officer

State of California—Health and Human Services Agency
California Department of Public Health

EDMUND G. BROWN JR.
Governor

December 7, 2012

Sarah Cherney
Pace Analytical Services, Inc.- Minneapolis
1700 Elm Street, SE, Suite 200
Minneapolis, MN 55414

Dear Sarah Cherney: Certificate No 01155CA

Enclosed is an amended copy of your certificate.

If you have any questions, please contact our office at (510) 620-3155.

Sincerely,

David Mazzera, Ph.D., Assistant Division Chief
Division of Drinking Water and Environmental Management

NELAP RECOGNIZED TNI ACCREDITATION BODY

Certifies That

65-00282

Pace Analytical Services Inc - Pittsburgh

1638 Roseytown Suites 2, 3, & 4, Greensburg, PA 15601

Having duly met the requirement of
The act of June 29, 2002 (P.L. 596, No. 90)
dealing with Environmental Laboratories Accreditation
(27 Pa. C.S. §§4104-4113) and the
National Environmental Laboratory Accreditation Program Standard

is hereby approved as an

Accredited Laboratory

As more fully described in the attached Scope of Accreditation

Expiration Date: **03/31/2014**

Certificate Number: **012**

Aaren S. Alger, Chief
Laboratory Accreditation Program
Bureau of Laboratories

Continued accreditation status depends on successful ongoing participation in the program
Certificate not transferable Surrender upon revocation
To be conspicuously displayed at the Laboratory
Not valid unless accompanied by a valid Scope of Accreditation
Shall not be used to imply endorsement by the Commonwealth of Pennsylvania
Customers are urged to verify the laboratory's current accreditation status
PA DEP is a NELAP recognized accreditation body

RE: Updated Fields of Accreditation (A13-00282-08)
DEP Lab I.D. No. 65-00282
PADWIS I.D. No. 65282

Dear Mr. Leeke:

On December 17, 2013, the Laboratory Accreditation Program of the Pennsylvania Department of Environmental Protection ("Department") received a Part 4—Add FOA Application from your laboratory. The Department reviewed this application and associated materials. Your accreditation status in the Pennsylvania Environmental Laboratory Accreditation Program has changed due to your application request. Your current accreditation status is as shown on the attached listing. That list of accredited fields of testing replaces all previous lists.

Your laboratory shall not use this Scope of Accreditation to imply endorsement by the Department. In order to maintain accreditation, your laboratory must remain in compliance with Departmental regulations.

Any person aggrieved by this action may appeal, pursuant to Section 4 of the Environmental Hearing Board Act, 35 P.S. Section 7514, and the Administrative Agency Law, 2 Pa.C.S. Chapter 5A, to the Environmental Hearing Board, Second Floor, Rachel Carson State Office Building, 400 Market Street, P.O. Box 8457, Harrisburg, PA 17105-8457, 717-787-3483. TDD users may contact the Board through the Pennsylvania Relay Service, 800-654-5984. Appeals must be filed with the Environmental Hearing Board within 30 days of receipt of written notice of this action unless the appropriate statute provides a different time period. Copies of the appeal form and the Board's rules of practice and procedure may be obtained from the Board. The appeal form and the Board's rules of practice and procedure are also available in Braille or on audiotape from the Secretary to the Board at 717-787-3483. This paragraph does not, in and of itself, create any right of appeal beyond that permitted by applicable statutes and decisional law.

IF YOU WANT TO CHALLENGE THIS ACTION, YOUR APPEAL MUST REACH THE BOARD WITHIN 30 DAYS. YOU DO NOT NEED A LAWYER TO FILE AN APPEAL WITH THE BOARD. IMPORTANT LEGAL RIGHTS ARE AT STAKE, HOWEVER, SO YOU SHOULD SHOW THIS DOCUMENT TO A LAWYER AT ONCE. IF YOU CANNOT AFFORD A LAWYER, YOU MAY QUALIFY FOR FREE PRO BONO REPRESENTATION. CALL THE SECRETARY TO THE BOARD (717-787-3483) FOR MORE INFORMATION.

If you have any questions regarding your laboratory's accreditation status, please contact Ronald L. Houck, Jr. at 717-346-8210.

Sincerely,

Aaren Alger

Aaren S. Alger, Chief
Laboratory Accreditation Program

NELAP - RECOGNIZED

CALIFORNIA STATE

ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM BRANCH

CERTIFICATE OF NELAP ACCREDITATION

Is hereby granted to

Weck Laboratories, Inc.

14859 East Clark Avenue

City of Industry, CA 91745

Scope of the Certificate is limited to the
"NELAP Fields of Accreditation"
which accompany this Certificate.

Continued accredited status depends on successful
ongoing participation in the program.

This Certificate is granted in accordance with provisions of
Section 100825, et seq. of the Health and Safety Code.

Certificate No.: **04229CA**

Expiration Date: **10/31/2013**

Effective Date: **11/1/2012**

Richmond, California
subject to forfeiture or revocation

14859 East Clark Avenue
City of Industry, CA 91745
Phone: (626) 336-2139

Certificate No.: 04229CA
Renew Date: 10/31/2013

101 - Microbiology of Drinking Water

101.010	001	SM9215B	Heterotrophic Bacteria
101.020	001	SM9221A,B	Total Coliform
101.021	001	SM9221E (MTF/EC)	Fecal Coliform
101.060	002	SM9223	Total Coliform
101.060	003	SM9223	E. coli
101.120	001	SM9221A,B,C	Total Coliform (Enumeration)
101.130	001	SM9221E (MTF/EC)	Fecal Coliform (Enumeration)
101.160	001	SM9223	Total Coliform (Enumeration)
101.200	001	SM9223B	E. coli (Enumeration)
101.210	001	SM9221B.1/SM9221F	E. coli (Enumeration)

102 - Inorganic Chemistry of Drinking Water

102.020	001	EPA 180.1	Turbidity
102.030	001	EPA 300.0	Bromide
102.030	003	EPA 300.0	Chloride
102.030	005	EPA 300.0	Fluoride
102.030	006	EPA 300.0	Nitrate
102.030	007	EPA 300.0	Nitrite
102.030	010	EPA 300.0	Sulfate
102.040	001	EPA 300.1	Bromide
102.040	002	EPA 300.1	Chlorite
102.040	003	EPA 300.1	Chlorate
102.040	004	EPA 300.1	Bromate
102.045	001	EPA 314.0	Perchlorate
102.047	001	EPA 331.0	Perchlorate
102.048	001	EPA 332.0	Perchlorate
102.050	001	EPA 335.4	Cyanide
102.060	001	EPA 353.2	Nitrate calc.
102.061	001	EPA 353.2	Nitrite
102.070	001	EPA 365.1	Phosphate, Ortho
102.100	001	SM2320B	Alkalinity
102.110	001	SM2330B	Corrosivity (Langlier Index)
102.120	001	SM2340B	Hardness

102.130	001	SM2510B	Conductivity
102.140	001	SM2540C	Total Dissolved Solids
102.163	001	SM4500-Cl G	Chlorine, Free and Total
102.180	001	SM4500-ClO2 D	Chlorine Dioxide
102.190	001	SM4500-CN E	Cyanide, Total
102.192	001	SM4500-CN G	Cyanide, amenable
102.210	001	SM4500-H+ B	pH
102.263	002	SM5310C	TOC/DOC
102.270	001	SM5540C	Surfactants
102.280	001	SM5910B	UV254
102.520	001	EPA 200.7	Calcium
102.520	002	EPA 200.7	Magnesium
102.520	003	EPA 200.7	Potassium
102.520	004	EPA 200.7	Silica
102.520	005	EPA 200.7	Sodium
102.520	006	EPA 200.7	Hardness (calc.)
102.546	001	EPA 326.0	Bromate
102.546	002	EPA 326.0	Bromide
102.546	003	EPA 326.0	Chlorite
102.551	002	SM4500-Cl G	Chlorine, Free, Combined, Total
102.555	002	EPA 415.3	SUVA
102.555	003	EPA 415.3	TOC/DOC

103 - Toxic Chemical Elements of Drinking Water

103.130	001	EPA 200.7	Aluminum
103.130	003	EPA 200.7	Barium
103.130	004	EPA 200.7	Beryllium
103.130	005	EPA 200.7	Cadmium
103.130	007	EPA 200.7	Chromium
103.130	008	EPA 200.7	Copper
103.130	009	EPA 200.7	Iron
103.130	011	EPA 200.7	Manganese
103.130	012	EPA 200.7	Nickel
103.130	015	EPA 200.7	Silver
103.130	017	EPA 200.7	Zinc
103.140	001	EPA 200.8	Aluminum
103.140	002	EPA 200.8	Antimony
103.140	003	EPA 200.8	Arsenic
103.140	004	EPA 200.8	Barium
103.140	005	EPA 200.8	Beryllium
103.140	006	EPA 200.8	Cadmium

103.140	007	EPA 200.8	Chromium
103.140	008	EPA 200.8	Copper
103.140	009	EPA 200.8	Lead
103.140	010	EPA 200.8	Manganese
103.140	011	EPA 200.8	Mercury
103.140	012	EPA 200.8	Nickel
103.140	013	EPA 200.8	Selenium
103.140	014	EPA 200.8	Silver
103.140	015	EPA 200.8	Thallium
103.140	016	EPA 200.8	Zinc
103.160	001	EPA 245.1	Mercury
103.310	001	EPA 218.6	Chromium (VI)

104 - Volatile Organic Chemistry of Drinking Water

104.030	004	EPA 504.1	EDB and DBCP
104.040	000	EPA 524.2	Volatile Organic Compounds
104.040	059	EPA 524.2	Federal regulated VOCs, excluding vinyl chloride
104.040	060	EPA 524.2	Federal unregulated VOCs
104.045	005	EPA 524.2	Trihalomethanes
104.050	006	EPA 524.2	Trichlorotrifluoroethane
104.050	011	EPA 524.2	Oxygenates

105 - Semi-volatile Organic Chemistry of Drinking Water

105.040	000	EPA 508	Chlorinated Pesticides
105.040	016	EPA 508	PCBs as Aroclors (screen)
105.082	009	EPA 515.3	Chlorinated Acids
105.090	029	EPA 525.2	Polynuclear Aromatic Hydrocarbons
105.090	030	EPA 525.2	Adipates
105.090	031	EPA 525.2	Phthalates
105.090	032	EPA 525.2	Other Extractables
105.090	034	EPA 525.2	Pesticides
105.100	000	EPA 531.1	Carbamates
105.120	001	EPA 547	Glyphosate
105.140	001	EPA 548.1	Endothall
105.150	001	EPA 549.2	Diquat
105.170	031	EPA 551.1	Disinfection Byproducts
105.200	009	EPA 552.2	Haloacetic Acids
105.220	001	EPA 632	Diuron
105.230	001	EPA 1613	2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD)

106 - Radiochemistry of Drinking Water

106.010	001	EPA 900.0	Gross Alpha

106.010	002	EPA 900.0	Gross Beta
106.092	001	EPA 200.8	Uranium
106.270	001	SM7110C	Gross Alpha
106.610	001	SM7500-Rn	Radon-222

107 - Microbiology of Wastewater

107.010	001	SM9215B	Heterotrophic Bacteria
107.020	001	SM9221B	Total Coliform
107.030	001	SM9221B	Total Coliform with Chlorine Present
107.040	001	SM9221C,E (MTF/EC)	Fecal Coliform
107.050	001	SM9221E	Fecal Coliform with Chlorine Present
107.100	001	SM9230B	Fecal Streptococci
107.100	002	SM9230B	Enterococci
107.242	001	Enterolert	Enterococci
107.245	001	SM9223	E. coli

108 - Inorganic Chemistry of Wastewater

108.090	001	EPA 160.4	Residue, Volatile
108.110	001	EPA 180.1	Turbidity
108.112	001	EPA 200.7	Boron
108.112	002	EPA 200.7	Calcium
108.112	003	EPA 200.7	Hardness (calc.)
108.112	004	EPA 200.7	Magnesium
108.112	005	EPA 200.7	Potassium
108.112	006	EPA 200.7	Silica
108.112	007	EPA 200.7	Sodium
108.113	001	EPA 200.8	Boron
108.113	002	EPA 200.8	Calcium
108.113	003	EPA 200.8	Magnesium
108.113	004	EPA 200.8	Potassium
108.113	005	EPA 200.8	Silica
108.113	006	EPA 200.8	Sodium
108.120	001	EPA 300.0	Bromide
108.120	002	EPA 300.0	Chloride
108.120	003	EPA 300.0	Fluoride
108.120	004	EPA 300.0	Nitrate
108.120	005	EPA 300.0	Nitrite
108.120	006	EPA 300.0	Nitrate-nitrite
108.120	008	EPA 300.0	Sulfate
108.121	001	EPA 300.1	Bromide
108.183	001	EPA 335.4	Cyanide, Total

108.200	001	EPA 350.1	Ammonia
108.211	001	EPA 351.2	Kjeldahl Nitrogen
108.232	001	EPA 353.2	Nitrate-nitrite
108.232	002	EPA 353.2	Nitrite
108.260	001	EPA 365.1	Phosphate, Ortho
108.261	001	EPA 365.1	Phosphorus, Total
108.264	001	EPA 365.3	Phosphate, Ortho
108.265	001	EPA 365.3	Phosphorus, Total
108.323	001	EPA 410.4	Chemical Oxygen Demand
108.362	001	EPA 420.4	Phenols, Total
108.381	001	EPA 1664A	Oil and Grease
108.385	001	SM2120B	Color
108.410	001	SM2320B	Alkalinity
108.420	001	SM2340B	Hardness (calc.)
108.430	001	SM2510B	Conductivity
108.440	001	SM2540B	Residue, Total
108.441	001	SM2540C	Residue, Filterable
108.442	001	SM2540D	Residue, Non-filterable
108.443	001	SM2540F	Residue, Settleable
108.465	001	SM4500-Cl G	Chlorine
108.473	001	SM4500-CN G	Cyanide, amenable
108.490	001	SM4500-H+ B	pH
108.531	001	SM4500-O G	Dissolved Oxygen
108.560	001	SM4500-SO3 B	Sulfite
108.580	001	SM4500-S= D	Sulfide
108.590	001	SM5210B	Biochemical Oxygen Demand
108.591	001	SM5210B	Carbonaceous BOD
108.601	001	SM5220C	Chemical Oxygen Demand
108.611	001	SM5310C	Total Organic Carbon
108.620	001	SM5320B	Total Organic Halides
108.640	001	SM5540C	Surfactants

109 - Toxic Chemical Elements of Wastewater

109.010	001	EPA 200.7	Aluminum
109.010	002	EPA 200.7	Antimony

City of Industry, CA 91745-1396

Dear Alfredo E. Pierri:

Certificate No. 1132

This is to advise you that the laboratory named above continues to be certified as an environmental testing laboratory pursuant to the provisions of the Health and Safety Code (HSC), Division 101, Part 1, Chapter 4, Section 100825, et seq. Certification for all currently certified Fields of Testing that the laboratory has applied for renewal shall remain in effect until **3/31/2014** unless it is revoked.

Please note that the renewal application for certification is subject to an on-site process, and the continued use of this certificate is contingent upon:

* **successful completion of the on-site process;**
* **acceptable performance in the required proficiency testing (PT) studies;**
* **timely payment of all fees, including an annual fee due before March 31, 2013;**
* **compliance with Environmental Laboratory Accreditation Program Branch (ELAPB); statutes (HSC, Section 100825, et seq.) and Regulations (California Code of Regulations (CCR),Title 22, Division 4, Chapter 19).**

An updated certificate of the "Fields of Testing" will be issued to the laboratory upon successful completion of the on-site process.

The application for the renewal of this certificate must be received before the expiration date to remain in force according to the HSC100845(a).

Please note that the laboratory is required to notify ELAPB of any major changes in the laboratory such as the transfer of ownership, change of laboratory director, change in location, or structural alterations which may affect adversely the quality of analyses (HSC, Section 100845(b)(d)). Please include the above certificate number in all your correspondence with ELAPB.

If you have any questions, please contact ELAPB at (510) 620-3155.

Sincerely,

George C. Kulasingam

CERTIFICATE OF ENVIRONMENTAL ACCREDITATION

Is hereby granted to

Weck Laboratories, Inc.

14859 East Clark Avenue

City of Industry, CA 91745

Scope of the certificate is limited to the
"Fields of Testing"
which accompany this Certificate.

Continued accredited status depends on successful completion of on-site, proficiency testing studies, and payment of applicable fees.

This Certificate is granted in accordance with provisions of Section 100825, et seq. of the Health and Safety Code.

Certificate No.: **1132**

Expiration Date: **3/31/2014**

Effective Date: **4/1/2012**

Richmond, California
subject to forfeiture or revocation

City of Industry, CA 91745

Dear Alfredo Pierri: Certificate No. 04229CA

This is to advise you that the laboratory named above has been accredited under National Environmental Laboratory Accreditation Program (NELAP) as an environmental testing laboratory pursuant to the provisions of the Health and Safety Code (HSC), Division 101, Part 1, Chapter 4, Section 100825, *et seq.*

The Fields of Accreditation for which this laboratory has been accredited are enclosed. The certificate shall remain in effect until **October 31, 2014** unless revoked by California Environmental Laboratory Accreditation Program Branch (ELAPB) or withdrawn at your written request. To maintain accreditation, the laboratory shall comply with the National Environmental Laboratory Accreditation Conference (NELAC) Standards and all associated California ELAPB regulations and statutes.

The application for renewal of this certificate must be received before the expiration date of this certificate to remain in force according to the HSC 100847(a).

Please note that your laboratory is required to notify California ELAPB of any major changes in key accreditation criteria within 30 calendar days of the change. This written notification includes, but is not limited to, changes in ownership, location, key personnel, and major instrumentation (HSC 100847(b), (c), (d), and NELAC Standard Section 4.3.2). The certificate must be returned to California ELAPB upon loss of accredited status.

Your continued cooperation with the above requirements is essential for maintaining the high quality of the data produced by environmental laboratories accredited by the State of California.

If you have any questions, please contact Bill Walker at (818) 551-2012.

Sincerely,

Fred Choshe for

David Mazzera, Ph.D., Assistant Division Chief
Division of Drinking Water and Environmental Management

3.0 STATEMENT OF POLICY

3.1. INTRODUCTION

Eurofins Eaton Analytical, Inc. (EEA) is a premier TNI-NELAC Approved Lab, full-service drinking water and wastewater laboratory that serves a national and international clientele. EEA is located at 750 Royal Oaks Drive, Suite 100, Monrovia, CA 91016 and is an entity that can be held legally responsible. EEA provides organic, inorganic, microbial, and radiochemical analyses in support of the Safe Drinking Water Act (SDWA), Clean Water Act (CWA), National Pollutant Discharge Elimination EEA Systems (NPDES), Resource Conservation and Recovery Act (RCRA), Food and Drug Administration (FDA), and the World Health Organization (WHO) as well as the EPA Unregulated Contaminant Monitoring Regulation (UCMR) Programs. The Quality Assurance Project Plan (QAPP) for the UCMR program is discussed in a separate document as an addendum to the laboratory's comprehensive Quality Manual (QM). The essential elements of the Quality Systems Program of EEA and the quality control procedures utilized by the laboratory to ensure compliance to the UCMR program requirements are discussed in the UCMR QAPP. UCMR QAPPs are developed for specific UCMR programs.

EEA takes an active role in supporting the promulgation of improved methodologies and the practice of differentiating laboratories based on quality of data. EEA participates in the methods development and validation of Standard Methods.

3.2. QUALITY POLICY

Management's commitment to quality and to the management system is stated in the Quality Policy below, which is upheld through the application of related policies and procedures described in EEA's ***Quality Manual***, SOPs and policies.

The foundation of the quality policy lies in the involvement and continuous improvement activities of all aspects at EEA. A system of monitoring, auditing, and reviewing processes is used to bring to light the opportunities for improvement.

The quality policy is signed and dated, and is issued under the authority of the highest level of laboratory management, which demonstrates management's commitment to integrity, ethics, the quality system and associated standards.

Quality Policy Statement

The objective of the quality system and the commitment of management is to consistently provide our customers with data of known and documented quality that meets their requirements. EEA is committed to the production of quality analytical data. The methods by which this is ensured are: 1) meeting or exceeding method performance criteria, 2) providing deliverables to our clients in a timely manner and 3) fostering a spirit of continuous improvement in all areas of management and operations. Our policy is to use good professional practices, to maintain quality, to uphold the highest quality of service, and to comply with the TNI Standard and ISO 17025. The laboratory ensures the personnel are free from any commercial, financial, and other undue pressures, which might adversely affect the quality of work. This policy is implemented and enforced through unequivocal commitment of management, at all levels, to the Quality Assurance (QA) principles and practices outlined in this manual. However, the primary responsibility for quality rests with each individual within the laboratory organization. Every laboratory employee must ensure that the generation and reporting of quality analytical data is a fundamental priority. Every laboratory employee is required to familiarize themselves with the quality documentation and to implement the policies and procedures in their work. All employees are trained annually on ethical principles and procedures surrounding the data that is generated. The laboratory maintains a strict policy of client confidentiality.

Ed Wilson
Laboratory Director

This Quality Manual defines the performance criteria and support procedures by which quality analytical data are generated. Standard Operating Procedures (SOPs) for individual analytical methodologies supplement this Quality Manual. Together they provide the documentation framework for ensuring the generation of uniform, comparable and quality data over time.

The foundation of the quality policy is in the involvement and continuous improvement activities of all personnel at EEA. Opportunities for improvement are showcased with a system of monitoring, auditing, and reviewing processes. The spirit of innovation is encouraged and viewed as paramount to the continued success of the laboratory in serving its clients.

3.3. MISSION STATEMENT

EEA will contribute to global health and safety by providing customers with high quality laboratory and advisory services whilst creating opportunities for EEA employees and generating sustainable shareholder value. EEA will provide outstanding client service and data of known and documented quality to all clients at all times.

3.4. CODE OF ETHICS AND POLICY/DATA INTEGRITY PROCEDURES

EEA was a founding member (1989) of actLABS, the California Association of Testing Laboratories and drafted one of the first lab ethics policies for actLABS. actLABS subsequently became part of ACIL (American Council of Independent Labs). Beginning in 1997 our increased geographic client base required us to give up our actLABS membership.

As a former actLABS member and a current TNI (the NELAC Institute) accredited laboratory, EEA is committed to ensuring the integrity of generated data, meeting the quality needs of clients, and setting high quality and ethical standards in the environmental industry. EEA is committed to managing its businesses by agreeing to:

- Produce results that are accurate and include QA/QC information which meets client predefined Data Quality Objectives.
- Present services in a confidential, honest, and forthright manner.
- Provide employees with guidelines and an understanding of the ethical and quality standards of our industry.
- Operate our facilities in a manner that protects the environment and the health and safety of employees and the public.
- Operate the laboratory to ensure its personnel are free from any commercial, financial and other undue pressure that might adversely affect the quality of the work.
- Obey all pertinent federal, state, and local laws and regulations, and encourage other members of our industry to do the same.
- Educate clients as to the extent and kinds of services available.

In addition any employee of EEA identified as not conforming to the code of ethics of the laboratory, committing fraud or improper data manipulation, falsifying data, or deviating from the contractual requirements will be subject to disciplinary procedures, including suspension and up to termination of employment. Any supervisor or employee applying undue pressure to another coworker that might adversely affect the quality of the work (TNI-EL-V1M2- 2009-4.1.5.b) (ISO/IEC 17025:2005(E)-4.1.5.b) will be subject to the same disciplinary procedures outlined above.

In order to meet the requirements of the TNI data integrity program (TNI-EL-V1M2-2009-5.2.7), the laboratory implements a proactive program for the prevention and detection of improper, unethical or illegal action. This program includes training courses on Laboratory Ethics and Data Integrity Procedures, and educating all personnel on questionable practices. Details of the Laboratory Ethics and Data Integrity Procedures are found in the laboratory SOP. The laboratory SOP includes the implementation of Data Integrity Procedures including:

- Management Responsibilities on Data Integrity Procedures/Signed Contract/Ethics Agreement for all laboratory personnel [TNI-EL-V1M2-2009-4.2.8.1, 4.2.8.1a, 4.2.8.1b].
- Control and documentation – Internal Audit/Periodic Monitoring of Data Integrity/Evidence of Vulnerabilities [TNI-EL-V1M2-2009-4.14.2, 4.14.3][ISO/IEC 17025:2005(E)- 4.14.2, 4.14.3].
- Data Integrity Training and documentation of Examples of Improper Practices in the Laboratory Ethics SOP [TNI-EL-V1M2-2009-5.2.7].

3.5. SERVICE TO THE CLIENT

The laboratory collaborates with clients and/or their representatives in clarifying their request and in monitoring of the laboratory performance related to their work. Each request is reviewed to determine the nature of the request and the laboratory's ability to comply with the request within the confines of prevailing statues and/or regulations without risk to the confidentiality of other clients.

3.5.1. **Client Confidentiality**

EEA recognizes its clients to be its contractors, the regulatory community, and the general public. The day to day operations are defined with considerations to the needs, goals and health of all clients. Protection of clients' confidential information and proprietary rights are considered. Where data are provided for external audits or for other similar reasons, the client's name and identity are concealed as necessary to protect client-confidential information.

In the event that the laboratory transfers ownership or goes out of business, the laboratory will notify all clients to ensure that records are maintained or transferred according to the client's instructions [TNI-EL-V1M2-2009-4.13.3.h].

3.6. REVIEW OF REQUESTS AND CONTRACTS/CONTRACT AMENDMENTS

EEA agrees to assert competency only for work for which adequate preparation has been made. Before commencing new work, the laboratory reviews all new work to ensure that it has the appropriate capability, facilities, resources, and the test method is applicable to the customer's needs. This process assures that all work will be given adequate attention without shortcuts that may compromise data quality.

A contract may be any written or oral agreement to provide a client with environmental testing. The laboratory reviews contracts and informs clients if there are any potential conflicts, deficiencies, lack of accreditations or inability to complete client work. The review also covers any work that will be subcontracted by the laboratory.

3.6.1. **Procedure for the Review of Work Requests**

3.6.1.1. Requests, tenders and contracts received by the laboratory are reviewed to ensure that the laboratory has the necessary personnel, information resources, facilities, equipment, PT, MDLs, QC and current applicable accreditation status [TNI-EL-V1M2-2009-4.4.1][ISO/IEC 17025:2005(E)-4.4.1].

3.6.1.2. For new clients and comprehensive testing, contracts are generated and appropriate lab personnel, such as the Lab Director or Technical Director, review the Contracts to assure that the lab is capable of providing testing prior to the start of work [TNI-EL-V1M2-2009-4.4.1][ISO/IEC 17025:2005(E)-4.4.1].

3.6.1.3. For repetitive, routine tasks the review needs to be made only at the initial inquiry stage or on granting of the contract for ongoing routine work performed under a general agreement with the client, provided that the client's requirements remain unchanged.

3.6.1.4. For any contract amendment for TNI compliance, the laboratory repeats the review process. The client is informed of any deviation from the contract including the test method or sample handling processes. If a contract needs to be amended after work has commenced, the same contract review process is reviewed and amendments are communicated to all affected personnel. If the laboratory's accreditation is suspended, revoked, or voluntarily withdrawn, the laboratory reports to clients any applicable changes of its accreditation status.

3.6.1.5. The designated Project Manager (PM) reviews client samples received by the laboratory and logged in the LIMS. Review of logged tests and methods are documented in the Sample Acknowledgement Report by affixing the PM's signature and/or initials and date of review. A Sample Acknowledgement Report is sent to the client to document approval of LOGGED samples and methods of analysis.

3.6.1.6. Refer to the Nonmethod 26 SOP for detailed Contract Review procedures.

3.6.2. Documentation of Review

3.6.2.1. Records of reviews, including any significant changes, shall be maintained. Records shall also be maintained of pertinent discussions with a client relating to the client's requirements or the results of the work during the period of execution of the contract.

3.7. EEA STANDARD POLICY ON RESOLUTION OF COMPLAINTS

3.7.1. EEA reviews all complaints and determines appropriate action.

3.7.2. EEA will, if it is feasible and within holding times, arrange for repeat of all analyses that do not meet regulatory requirements. We hold ourselves responsible for reporting or re-reporting all results in a format that complies with regulatory requirements, and will make every attempt to correct and when feasible will repeat work at no additional charge for all analyses compromised due to laboratory error in shipping, sample preparation, or analysis. In the event of a sample loss within the required sample collection window, we will discuss with clients the merits of available options for flagging data versus re-sampling for either the individual parameter or the entire suite of samples. In all circumstances, EEA will keep clients completely informed and aware of potential or actual problems as they arise, using e-mail or telephone.

3.7.3. Where a complaint or any other circumstance raises doubt concerning compliance with the laboratory's policies, with the requirement of the TNI and ISO 17025 Standards or otherwise concerning the quality of the laboratory's data, the EEA Quality Assurance Department will conduct an audit of the affected areas of activity.

3.7.4. Documentation of the complaints or initiating event, internal audit findings and resulting corrective action will be maintained by the EEA Quality Assurance Department (TNI-EL-V1M2-2009-4.11.3) (ISO/IEC 17025:2005(E)-4.11.3) and as appropriate be conveyed to the client.

3.8. CAPABILITIES

EEA has the capability to analyze drinking water and wastewater for clients in the private and public sector where work is dictated by the regulatory requirements for the Safe Drinking Water Act (SDWA), Resource Conservation and Recovery Act (RCRA), National Pollutant Discharge Elimination Systems (NPDES), Clean Water Act (CWA), Food and Drug Administration (FDA), World Health Organization (WHO) and the Superfund Amendments and Reauthorization Act (SARA) and the EPA Unregulated Contaminants Monitoring Regulations (UCMR) Program. Our specialized laboratory services include;

- Analysis and identification of inorganic & organic disinfection by-products, taste and odor compounds in drinking water
- Identification and quantitation of coliphage in drinking water and wastewater
- Comparability of alternate test procedures for drinking water and wastewater analysis.
- Analysis of emerging contaminants such as Pharmaceuticals and Personal Care Products (PPCPs), Endocrine Disrupter Compounds (EDCs), and perfluoro octanesulfonate (PFOS).
- Analysis of bottled water and beverage matrices for FDA and WHO regulated analyses.

3.9. CERTIFICATIONS

EEA is currently certified in 45 states and 2 territories to perform various analyses for regulated parameters. EEA is also NELAP accredited in 13 TNI states out of 14 TNI

States' accrediting bodies. EEA holds primary accreditation under California NELAP (01114 CA) and ELAP Program (Certificate No. 1422). Please refer to Table 3-1 for the list of the states, laboratory identification number, and the certification type. An updated list is available in the QA office.

A copy of EEA's NELAP Accreditation plus NELAP fields of accreditation (Fig. 4-3, Fig. 4-4) and a copy of the CA ELAP plus Fields of Testing are attached (Figures 4-5 and 14-6). The most recent certification is available in the QA office.

Arizona Dept of Health Services requires that a copy of EEA's AZ certification and License (AZ0778) be attached in the Lab QM. See the AZ License and list of license parameters in Appendix I. The most recent certification is available in the QA office.

EEA may accept, analyze, and report results for samples from states in which it is not certified if the results are intended for non-regulatory monitoring.

When there is a change in lab location or ownership, the laboratory will report in writing to the accrediting authorities within 30 calendar days of the change.

3.10. SUBCONTRACTED LABORATORY WORK

3.10.1. On occasion laboratory work may be subcontracted to certified laboratories approved by EEA. The subcontractor laboratory will be approved only if the laboratory meets all the necessary certification requirements required by the state where the samples are collected. For example, samples collected from Alaskan Public Water supplies for compliance monitoring must be analyzed by a laboratory certified by the State of Alaska or the USEPA (18 AAC 80.255). For any part of testing covered under NELAP, the laboratory sends the work to a subcontractor accredited under NELAP or to a laboratory that meets applicable satisfactory and regulatory requirements for performing the test and submitting the results of the tests performed [TNI-EL-V1M2-2009-4.5.1][ISO/IEC 17025:2005(E)-4.5.1]. For ISO 17025 subcontracted work, EEA subcontracts work to an ISO 17025 subcontractor or qualified non ISO 17025 accredited subcontractor. Refer to the Nonmethod 31 SOP for the requirements for Non ISO 17025 accredited subcontractors.

3.10.2. Under no circumstances will work be subcontracted without client approval. The laboratory advises the client in writing of its intention to sub-contract any portion of the testing to another laboratory during the project bid proposal or purchase order procurement [TNI-EL-V1M2-2009-4.5.2][ISO/IEC 17025:2005(E)-4.5.2]. Test results provided by the subcontractor are identified by the subcontractor name or applicable accreditation number. The subcontractor shall report the results in writing or electronically [TNI-EL-V1M2-2009-5.10.6] [ISO/IEC 17025:2005(E)-5.10.6]. The laboratory shall make a copy of the subcontractor's report available to the client when requested by the client or when required by regulations.

3.10.3. Subcontracted work is documented in the chain of custody (COC). The COC and other appropriate records are included with the final data package as part of the final deliverables. To comply with California ELAP regulations (Title 22, Division 4, Chapter 19, Article 10, Section 64819), EEA's reports must include the original copies of reports prepared by the subcontracted laboratories. See section 14.4 for all the information required in the final test report.

3.10.4. To help ensure all subcontractors meet EEA's Data Quality Objectives and consistently produce documented data of known quality, EEA requires that the following documentation should be submitted by the vendor for review:

(1) NELAP laboratory accreditation, or state certifications that meet the applicable statutory and regulatory requirements
(2) Laboratory Quality Manual(QM) or at the minimum the signed cover page and table of contents of the lab QM (non-NELAP accredited facilities only)
(3) Notify EEA of 2 failed Proficiency Testing (PT) results or any changes of certification status either suspension or revocation for any relevant tests, if applicable.
(4) Recent state onsite audit findings for the relevant methods and corrective action report, if applicable
(5) For Non-NELAP lab, a copy of Data Integrity/Ethics Policy, if available

3.10.5. At a minimum, the lab's NELAP accreditation or states certification status and the signed cover page and table of contents of the lab QM is verified.

3.10.6. Data deliverables must meet EEA's project needs and requirements. EEA assumes responsibility to the client for the subcontractor's work, except in the case where a client or a regulating authority specified which subcontractor is to be used [TNI-EL-V1M2-2009-4.5.3][ISO/IEC 17025:2005(E)-4.5.3]. At a minimum, laboratory deliverables submitted to EEA must include final report, QC results and acceptance limits. Level 4 data deliverables may be requested by EEA for review as needed. Onsite audit of subcontract laboratory may also be conducted by EEA as needed.

3.10.7. Project managers and the designated subcontracting administrator must ensure all applicable quality documents specified in section 3.10.4 to evaluate subcontractor's qualifications are submitted to EEA for review by the subcontracting administrator. The subcontracting administrator will ensure that all approved subcontract labs and EEA's representatives have signed the required Subcontract Vendor Agreement/checklist. Before subcontracting samples, the designated subcontracting administrator shall review certifications to ensure that the laboratory's subcontractor's certification/ accreditation is current. If certification is not current, the subcontracting administrator shall contact the vendor for a current copy of the vendor's certification before shipping samples.

3.10.8. A register of all subcontractors and a record of evidence (such as NELAP accreditation or appropriate compliance to applicable regulatory requirements) are kept by the designated subcontracting administrator [TNI-EL-V1M2-2009-4.5.4][(ISO/IEC 17025:2005(E)-4.5.4]. A list of subcontracted laboratories approved by EEA is available in the server.

3.10.9. For samples originating in Massachusetts and subcontracted to another lab, EEA must identify, in writing, those samples needing special reports (e.g. MCL exceedance). The subcontract laboratory is responsible for notifying EEA and Massachusetts DEP of any MCL exceedances within 24 hours of obtaining valid data.

3.10.10. Refer to the Nonmethod 31 SOP for detailed Subcontracting procedures.

3.11. FACILITIES

3.11.1. ACCOMODATIONS

EEA's main laboratory is located at 750 Royal Oaks Drive, Suite 100 in Monrovia, California. It has more than 20,000 square feet of analytical laboratory workspace plus almost 15,000 square feet of support space with a staff of 109 in 2011. Figure 3-1 and Figure 3-2 contain the Floor Plans for the first and second floors, respectively of the Monrovia facility.

The Monrovia facility is controlled by access control locks which provide entry through plastic keycards stored with digital signatures of each employee.

Departments of the Main Laboratory include:

Asbestos
GC extractables/volatiles
GC/MS extractables/volatiles
Ion Chromatography
LC/MS/MS Extractables
Metals/Metals Prep

Microbiology
Organic extractions
Radiochemistry
Sample Disposal
Sample Receipt
Shipping – sample bottle preparation
Wet Chemistry (including General Physical)

In addition to the Monrovia facility, there are three service centers that are a part of the laboratory.

- The Inland Empire/Microbiology Lab located at 1012 E. Cooley Dr., Ste P, Colton, California, 92324;
- The Southwest Center located at 15953 N. Greenway Hayden Loop, Ste. C, Scottsdale, Arizona 85260;
- The Northern California Center is located at 180 Blue Ravine Road, Suite A & B, Folsom, CA 95630.

The management systems that are compliant with TNI Standards and ISO 17025 that are documented in the laboratory Quality Manual covers work carried out in the Monrovia facility and in-house sampling procedures associated with field activities.

3.11.2. **ENVIRONMENTAL CONDITIONS**

3.11.2.1. The laboratory ensures that the laboratory environment conditions do not invalidate the results or adversely affect the required quality of any measurement.

3.11.2.2. The laboratory monitors, controls and records environmental conditions as required by the relevant specifications, methods and procedures, or where they influence the quality of the results.

3.11.2.3. Biological sterility and dust are monitored in microbiology to ensure that environmental conditions do not jeopardize the results of the environmental tests and/or calibrations. The laboratory micro walls, floors, work surfaces are non-absorbent and easy to clean and disinfect.

3.11.2.4. Incompatible areas such as Volatiles, Sample Extraction, Microbiology, culture handling or incubation, Radiochemistry preparation areas are separated to prevent cross-contamination.

3.11.2.5. The laboratory work spaces are adequate, and appropriately clean to support environmental testing and ensure an unencumbered work area.

Figure 3-1 Floor Plan First Floor

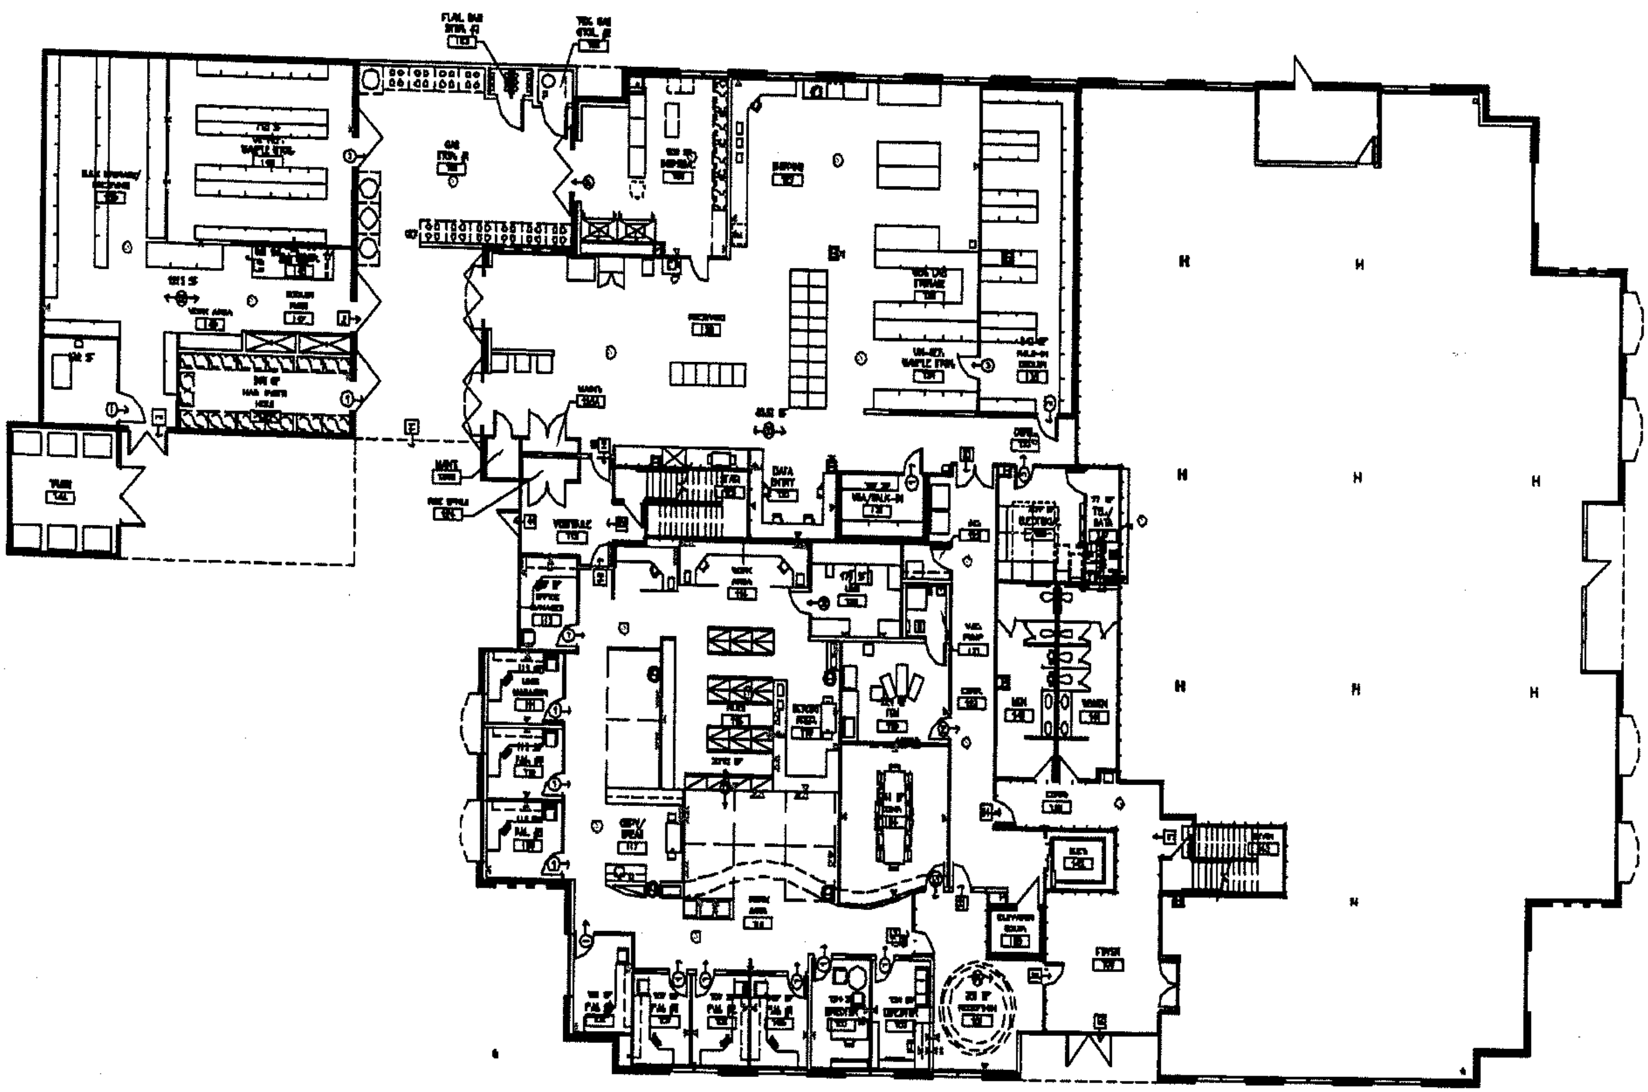

Figure 3-2 Floor Plan 2nd Floor

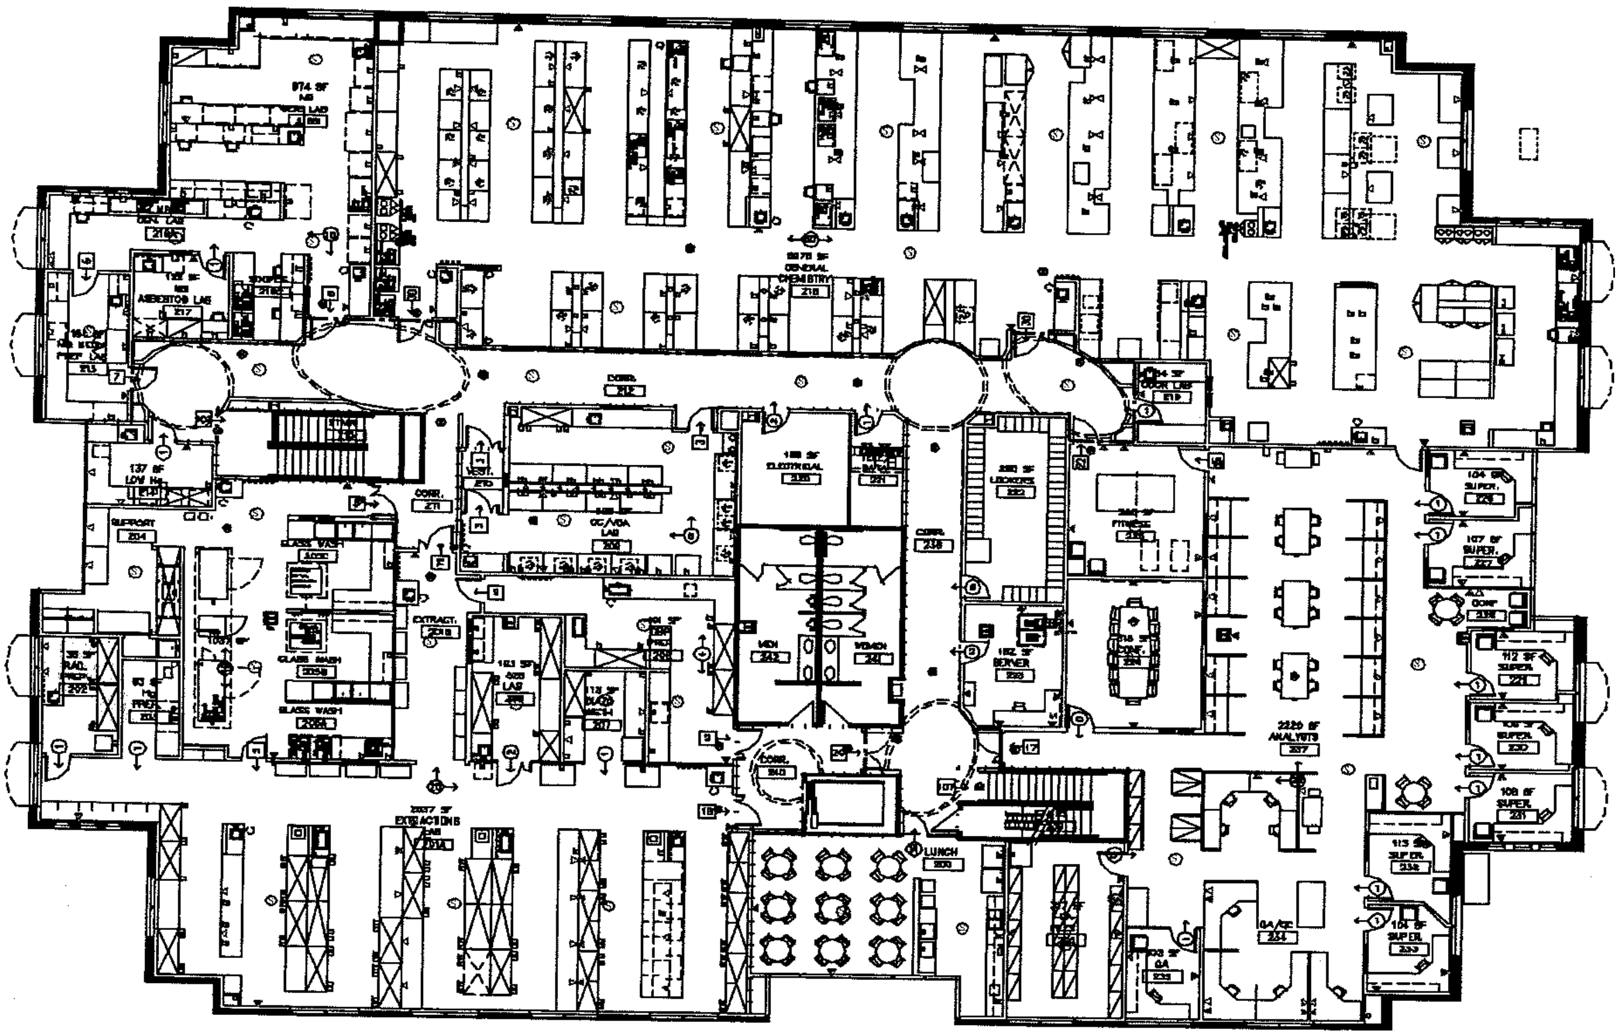

4.0 PROGRAM ORGANIZATION AND MANAGEMENT

All EEA's analysts and technicians analyzing drinking water samples meet the minimum qualifications specified in the Manual for the Certification of Laboratories Analyzing Drinking Water, Criteria and Procedures, Quality Assurance, 5th Edition. The organization and chain of command for the laboratory is shown in Figure 4-9. Details of assigned positions, responsibilities and qualifications for senior management personnel are summarized below. The laboratory is organized in such a way that managerial staff has the authority and resources needed to discharge their duties. Top Management is the Laboratory Director who makes decisions on policy, endorses the quality policy statement, and allocates resources to implement and maintain the quality system. The Technical Director, Quality Manager, Technical Managers, and deputies are part of the management staff. The Quality Manager reports directly to the EEA Laboratory Director and has the authority to make independent technical judgment not influenced by production, marketing and financing issues. Qualified supervisors are certified as to their educational and technical background and experience, to ensure that supervision is provided by persons familiar with the calibration or test methods and procedures, the objective of the calibration or test and the assessment of the results.

4.1. EEA'S LABORATORIES PERSONNEL

4.1.1. Laboratory Director: Mr. Ed Wilson

Mr. Wilson has over 35 years of environmental chemistry and laboratory management experience to the laboratory. He sets laboratory policy and is responsible for overall laboratory performance and direction. In his role as Lab Director, he has ultimate responsibility for ensuring the operational efficiency and accuracy of laboratory procedures, cost analysis, overhead control, marketing, and project management. His guided management principles are based on achieving outstanding Customer Service and Technical Excellence. Under his direction and leadership, EEA would have systems built on the most sophisticated information technology platform and would be proud to have the best technical staff in the industry.

4.1.2. Technical Director: Dr. Andrew Eaton

Dr. Andrew Eaton has over 30 years of analytical experience including over 20 years of managerial experience. In his capacity as Technical Director, Dr. Eaton certifies that personnel with appropriate educational and/or technical background perform all tests for which the laboratory is accredited. Such certification for each personnel is documented in the analyst's initial demonstration of capability (DOC) certification. The initial DOC certification statement was modified to include the certification for the analyst for having the appropriate educational and/or technical background. A copy of the certification statement is retained in the training files of each affected employee. Dr. Eaton is responsible for Project Management on large projects with significant technical issues, serves as a technical advisor to the laboratory staff and clients, works on special assignments such as productivity assessments and financial analyses, as well as marketing activities with clients whose projects are highly technical in nature. Dr. Eaton also serves as a member of the Joint Editorial Board for Standard Methods for the

Examination of Water and Wastewater (SM). In this capacity, he is responsible for recommending new methods for inclusion in SM and ensuring that all proposed methods include appropriate levels of QC and validation. He is a former member of the TNI Advocacy Committee. Formerly on the Board of actLABS, Dr. Eaton also served as a member of The Methods and Data Comparability Board, which reports to the National Water Quality Monitoring Council.

4.1.3. **Asbestos Technical Manager: Carol J. Belt**

Ms. Belt has over 30 years of environmental laboratory experience in EEA conducting microbiology and asbestos analyses. Her expertise includes analysis of drinking water and wastewater samples for microbiological testing and asbestos analysis. She is responsible for training analysts in various microbiological procedures and in the analytical method for the determination of asbestos fibers in water. As the Technical Manager for Asbestos analysis, Ms. Belt has the overall responsibility for the technical operation of the asbestos testing in the laboratory and currently oversees all aspects of the asbestos testing She is responsible for monitoring the performance of the entire procedure and accurate reporting of all samples received for asbestos analysis. She is also responsible to train other technicians on this methodology and to certify trained analysts as to their educational and technical background and demonstration of capability.

4.1.4. **Client Services Manager: Frederick Haley**

Mr. Haley has over 27 years of environmental laboratory experience. His experience has encompassed analytical method development for soils and water as well as development of mobile laboratory services. Mr. Haley has managed lab operations for both small and large lab settings. He oversaw the daily operations of a small satellite laboratory of 10 staff performing basic analytical methods and has also managed a large laboratory of over 150 personnel conducting wastewater, soil, hazardous waste and drinking water analysis. In addition Mr. Haley has managed projects requiring coordination of schedule, personnel, budget and compliance to technical specifications for local, state and federal agencies as well as private sector companies. Mr. Haley is responsible for the daily supervision of 7 project managers.

4.1.5. **Quality Manager/Regulatory Consulting Manager: Ms. Nilda B. Cox**

Ms. Cox has over 20 years of environmental experience in Quality Assurance/Quality Control including hazardous waste management and safety compliance in the laboratory. Her experience also includes eight years as senior chemist and supervisor of chemistry QA/QC Methods Development Group, and in-charge of the Industrial Hygiene Monitoring Program for a medical device company. Additional experience includes six years in Research and Development in the field of agriculture. Ms. Cox is responsible for providing QA solutions to our clients.

In addition to supporting internal QA/QC, Ms. Cox serves as a resource for numerous outside entities, providing consulting services in the area of QA/QC to assist them in the development of their own in-house QA Programs.

In the absence of the Quality Manager, Robert Dean and Yoon Cha are authorized as the Deputy Quality Managers.

4.1.6. Senior Project Manager/Deputy Technical Director: Linda Geddes

Ms. Geddes has over 30 years experience in the field of analytical chemistry related to environmental issues, including three years as the Quality Assurance Manager at another laboratory, over five years of experience in pharmaceutical chemistry, and 2 years as QA/QC Officer for EEA. Her experience has encompassed analytical methods development and validation for soils, sediments and water, maintaining a quality assurance program and managing Department of Defense site assessment projects. These projects have required coordination of schedule, personnel, budget, and compliance to technical specifications for local, state, and federal agencies, as well as private sector companies. These included compliance monitoring under the Coliform Rule, the Lead and Copper Rule, Phase II and V, the Information Collection Rule (ICR), and the Unregulated Contaminant Monitoring Rule (UCMR). Prior to becoming the Quality Assurance Officer, Ms. Geddes was a Project Manager at EEA for eight years.

In the absence of the Technical Director, Ms. Geddes is designated as the Deputy Technical Director.

4.1.7. Technical Manager/LCMS Supervisor: Mr. Ali Haghani

As EEA's Technical Manager/LCS Supervisor, Mr. Haghani is responsible for method development of new methods and for asset management and currently supervising 4 analysts. Mr. Haghani was previously responsible for overseeing six supervisors and a staff of over 50 analysts performing sample preparation and analysis of environmental samples for organics and a wide range of inorganic parameters. He was also responsible for the day-to-day scheduling of analysts workloads, providing guidance and technical expertise to the analyst, and checking the validity of their work. Mr. Haghani has over 17 years of experience in the environmental monitoring business and has technical expertise in inorganic and organic analytical chemistry.

4.1.8. Technical Manager/Extraction and GC/MS Supervisor: Mr. Charles Grady

Mr. Grady has over 20 years experience in environmental extraction, environmental wet chemistry, environmental GC and environmental GC/MS. He also has experience in hazardous waste, drinking water and waste water testing. Mr. Grady also has two years of experience as an instrument repair service technician.

As Technical Manager/Extraction and GC/MS Supervisor for EEA, Mr. Grady is responsible for supervising 18 analysts, meeting quality control and method requirements, scheduling work, recruiting and training staff, and managing the group budget. He works closely with Client Services, the Lab Directors and department managers to schedule incoming work and to meet QC requirements and specific client needs.

4.1.9. **Technical Manager/GC/HPLC Supervisor: Ms. Sophia Liang**

As EEA's Technical Manager or GC/HPLC supervisor, Ms. Liang is responsible for day to day supervision of a staff of 8 analysts performing organic analysis by GC and HPLC (High Performance Liquid Chromatography). Ms. Liang schedules analysts' workloads to ensure that holding times are not exceeded, approves final data, and insures that all QA guidelines are met. Ms. Liang has over 8 years of experience performing organic analyses.

4.1.10. **Technical Manager/Inorganic Supervisor: Mr. Walter Hsieh**

As EEA's Metals/Radiochemistry/Wet Chemistry supervisor, Mr. Hsieh is responsible for day to day supervision of a staff of 24 analysts performing inorganic analyses such as metals, radiochemistry and wet chemistry. Mr. Hsieh schedules analysts' workloads to ensure that holding times are not exceeded, approves final data, and insures that all QA guidelines are met. Mr. Hsieh has over 20 years experience performing metal and organic analyses in environmental laboratories.

4.1.11. **Technical Manager/Microbiology Supervisor: Ms. Polly Barrowman**

Ms. Barrowman has over 5 years of microbiology and biology experience. She obtained her BS in Biology and Chemistry at Western Michigan University in 2003 and her MS in Environmental Biology at University of Aberdeen, Scotland in 2005. She has been a Microbiologist at EEA's since June 2009, with experience performing water suitability, inhibitory residues, standard plate counts, and coliform analyses. Ms. Barrowman ensures that all holding times are not exceeded and that all QA guidelines are met. Ms. Barrowman is responsible for the daily supervision of a staff of 9 laboratory personnel.

4.1.12. **LIMS Manager: Mr. Ryan Chang**

Mr. Chang has over 15 years of IT experience including technical support for several nationally syndicated radio shows, website implementation for several fortune 1000 companies, intra and internet e-commerce development and was a webmaster for UCLA Business Law Courses. He is skilled in multiple server-side, client-side, database, web server, app-server and e-commerce languages. He holds a Bachelor's of Science in Computer Science and Engineering and a Bachelor of Arts in Economics both, from UCLA.

4.1.13. **Deputy Lab Director: Mr. James Hein**

Mr. Hein has over 30 years of environmental laboratory experience. His experience has encompassed analytical methods development for soils, sediments and water, the development of data assessment procedures for validation of analytical data, and the implementation of numerous bench scale treatment studies for the removal of various environmental pollutants.

He has managed projects requiring coordination of schedule, personnel, budget and compliance to technical specifications for local, state and federal agencies as well as private sector companies. In the absence of the Lab Director, Mr. Hein is designated as the Deputy Lab Director.

4.2. QUALITY SYSTEMS PROGRAM AND ITS MANAGEMENT

The Quality Systems Program is dynamic and is updated frequently when changes to policy and procedures are necessary. The Quality Manager has direct access to the highest level of management, which is the Laboratory Director, where decisions are made on laboratory policy or resources [TNI-EL-V1M2- 2009-4.1.7.1]. It is the responsibility of the Quality Manager to oversee all aspects of this program and document the participation of all staff members. In order to administer and manage this program, the Quality Manager must be knowledgeable in the TNI Quality Systems and ISO 17025 Current Standards and their implementation [TNI-EL-V1M2- 2009-4.1.7.1, 4.2.8.2]. Attendance at the TNI Interim and annual Conferences should be documented in the training files of the Quality Manager.

Vital areas of the Quality Systems Program include:

4.2.1. Preparing annual reports to management on QA related activities in the laboratory. Through the annual report, the Quality Manager notifies the laboratory management of deficiencies in the Quality Systems and monitors corrective actions. (Section 16.4) This includes a periodic QA report, reports on internal and external PT samples, and verbal transmittal of QA information to the Laboratory Director and group supervisors during a weekly staff meeting.

4.2.2. Coordinating analyses of Proficiency Testing (PT) (i.e. water supply study-WS, water pollution study-WP) or blind performance samples; investigating any problems associated with the results; reviewing results, problems and corrective actions with the analytical and supervisory staff; providing timely response to certification authorities with respect to any identified problem areas. (Section 16.3)

4.2.3. Implementing procedures that allow for adequate documentation and control of specific documents. These procedures use a unique identification system that allows for tracking and traceability of official copies and the time period the procedure or document was in force. To ensure that the Quality Manual and SOPs remain controlled documents, the master SOPs and Quality Manual (original official version of the SOP and Quality Manual) and copies of the SOP and Quality Manual will be identified. The cover page of each copy will contain a unique identification indicating that the document is controlled copy ___ of ____ copies, initialed and dated by the Quality Manager (or designee) in red ink. This ensures that the analyst is using the current version. Refer to the Nonmethod 25 SOP for detailed Document Control procedures.

4.2.3.1. The Quality Manual and Standard Operating Procedures (SOP) of EEA are reviewed and updated if needed at least once a year to ensure continuing suitability and compliance with applicable requirements. The laboratory's document control system allows for the amendment of documents by hand, pending the reissue of the documents. The changes are clearly marked, initialed and dated by the personnel that performed the original review. The revised document formerly reissued as soon as practicable [TNI-EL-V1M2- 2009-4.3.3.3, 4.3.3.1][ISO/IEC 17025:2005(E)-4.3.3.3, 4.3.3.1]. All appropriate laboratory personnel signs the Quality Manual Signature Page / SOP Training Documentation Form after the annual review of the Quality Manual / SOPs.

4.2.3.2. See Figure 4-1 QM Signature Page for a copy of the QM Signature Page. See Figure 4-2 SOP/Method Training Documentation for a copy of the SOP Training Documentation Form. See Table 4-1 for a list of SOPs.

4.2.3.3. A SOP/ QM Distribution Form is prepared for each SOP/ QM that includes the SOP/QM ID, control number, individual receiving the SOP/QM, date of issue and the date of completion of the analyst's SOP/QM training documentation.

4.2.4. Documenting participation and performance of the laboratory staff in initial and continuing training courses.

4.2.5. Overseeing and maintaining the training program files for each analyst at EEA.

4.2.6. Providing guidelines for the QS orientation program to newly hired personnel and ensuring that they are familiar with the quality systems program operating within the laboratory.

4.2.7. Interacting with auditors and certifying authorities for in-state programs, out-of-state programs, and internally to the laboratory. (16.2)

4.2.8. Serving as focal point for initiation, implementation, review and dissemination of QA/QC Guidelines to ensure that data quality meets the objectives of certifying authorities and maintaining documentation of those guidelines.

4.2.9. Maintaining copies of procedural write-ups and QA documentation files, and ensuring that all personnel working in the laboratory follow established standard operating procedures that do not compromise the quality of data submitted to clients or violate rules and guidelines from certifying agencies.

4.2.10. Ensuring that analysts are monitoring long-term quality control trends with quality control charts and insuring that corrective action is initiated whenever an out of control event occurs.

4.2.11. Ensuring that sample log-in and traceability are done correctly and that the chain of custody forms and other relevant documentation are properly maintained by periodic spot checks of the records.

4.2.12. Implementing a record management/archival system for control of laboratory notebooks; instrument logbooks; standard logbooks; records for data reduction, validation, storage, and reporting; training records for personnel no longer with the laboratory; outdated manuals and

SOPs; and the eventual removal of outdated documentation. Archived information is stored physically or electronically in-house for 3 months and then physical files are transferred off-site, for storage for 2 years for Arizona or 3 years for Wisconsin. Electronically scanned files are stored for 5 years as per NELAP, and additional 5 years as per Massachusetts, Hawaii and New York. All hard copies and electronic files for Asbestos test method are stored for 30 years.

4.2.13. Maintain a log of names, initials and signatures for all individuals responsible for signing or initialing any laboratory records is maintained by the QA group.

4.2.14. Writing or reviewing QA project specific plans.

4.2.15. Providing the staff with quality assurance information and updates.

4.2.16. Ensuring that all laboratory procedures currently in use are acceptable and will not compromise quality.

4.2.17. Where QA oversight is needed, the Quality Manager (or designee) functions independently from the laboratory operations. The Quality Manager evaluates data objectively and performs assessments without managerial influence. The Quality Manager may enlist the aid of various supervisors of the analytical groups in order to achieve these objectives. The Quality Manager and/or a designee should perform periodic audits of laboratory data or procedures to ensure that QA objectives are being met. The Quality Manager or designee must have a general knowledge of the analytical test methods for which the data review is performed and will arrange for or conduct annual internal audits per TNI-EL-V1M2-2009-4.1.7.1.e and 4.1.7.1.f.

4.2.17.1. Maintaining current certifications, licenses and accreditation materials. See section 3.9 for more information about certification.

4.3. STAFF RESPONSIBILITY

A comprehensive Quality Systems Program requires the involvement of all laboratory personnel. The level of involvement for each staff member is dependent upon his or her assignment within the laboratory. Laboratory analysts are responsible for quality control parameters that are done at the time of analysis. Laboratory management is responsible for monitoring and evaluating the results of the quality control procedures performed by the analysts.

The minimum level for qualifications, experience, and skills necessary for each position varies by job position. A list for each position is available in QA for review. The laboratory follows minimum requirements as per the EPA Drinking Water Manual and TNI Standards.

4.3.1. **Initial Training**

4.3.1.1. The objective for data generated by EEA is that the quality and consistency of the data produced be independent of the analyst performing the analysis. This can only occur when all analyses are performed using SOPs, and the analyst performing the procedure has been properly trained and has demonstrated proficiency with the analysis. This is accomplished at EEA by having a training checklist for each group or set of analyses within a group.

4.3.1.2. This checklist is followed for each trainee analyst by the group supervisor with the help of an assigned analyst mentor. The trainee is issued a set of training materials (i.e. safety information, SOP, Ethics SOP, method reference etc.) and is given hands-on training under the direct supervision of the mentor analyst or supervisor. Progress is monitored closely for the first three to six months by using frequent performance reviews, quality control check samples, performance audits and bench sheet reviews.

4.3.1.3. IDC Certification serves as a record of Authorization and Competence [TNI-EL-V1M2-2009-5.2.5][ISO/IEC 17025:2005(E)-5.2.5]. All Analysts, including contracted personnel when hired, are required to undergo the same training (IDC, MDL Studies, ability to achieve a low background, the precision and accuracy required by the method and satisfactory performance on a PT sample), and IDC Certificate of Competence [TNI-EL-V1M2-2009-5.2.1][ISO/IEC 17025:2005(E)-5.2.1]. A copy is filed in the analyst training record. Demonstration of Capability will also be done for analysts working as a unit. Examples are extraction analysts preparing the IDC and MDL samples and the prepared sample analyzed by the appropriate GC, GCMS, or HPLC analysts. IDC certification is completed for the group of analysts.

4.3.1.4. Initial training for a field sampling personnel is done through overall sampling procedure technique review and through duplicate samples for each new method and/or matrix that each of the field sampling personnel first performed.

For field sampling testing, DOC and MDL studies are performed initially and repeated at the frequency that the specific method requires.

4.3.2. On-going Training/Annual Competency Check

The laboratory performs an annual competency check for each analyst to ensure that each technical employee demonstrates an initial and ongoing proficiency for the tests performed by the technical employee.

On-going proficiency checks are conducted to ensure that the training of personnel is kept up-to-date by the following:

4.3.2.1. A certification that the technical personnel have read, understood and agreed to perform the most recent version of the test method (the approved method or standard operating procedure) and documentation of continued proficiency by at least one of the following once per year:

4.3.2.1.1. Acceptable performance of a blind sample (single blind to the analyst).

4.3.2.1.2. Another initial demonstration of method performance

4.3.2.1.3. Successful analysis of a blind performance sample on a similar test method using the same technology (e.g., GC/MS Volatiles by purge and trap for 524.2, 624 or 5030B/8260) would only require documentation for one of the test methods [TNI-EL-V1M3 to V1M4-ISO-2009]. The laboratory must determine the acceptable limits of the blind performance sample prior to analysis. The laboratory uses the Provider acceptable TNI limits of any blind PT sample that is used to document the annual proficiency documentation for each analyst.

4.3.2.1.4. At least four consecutive laboratory control samples with acceptable levels of precision and accuracy as per method specified precision and accuracy limits.

4.3.2.1.5. If the previous item cannot be performed, because spiking is not an option or QC samples not available, analysis of authentic samples that have been analyzed by another trained analyst with statistically identical results or analysis of Proficiency Test samples obtained from NIST approved providers can be done.

4.3.2.1.6. For specialized situations where extraction analysts have to do the sample preparation for LCS and MDL samples and the analyses of the prepared samples are done by the analysts belonging to another group, such as GC or GCMS areas, the group as a unit completes a Demonstration of Capability.

4.3.2.2. Evidence on file that demonstrates that each employee has read, understood, and is using the latest version of the laboratory's in-house SOP documentation and all other documentation, which relates to his/her job responsibilities.

4.3.2.3. Training courses or workshops on specific equipment, analytical techniques or laboratory procedures shall all be documented.

4.3.3. Training Records

A training file for each analyst and method is kept in the QA department along with a training history form completed at the inception of the present training program or at the time of employment. Each analyst's training file includes; a resume indicating the analyst's qualifications, experience, transcript of records, job description, and an initial demonstration of capability (IDC) and continuing demonstration of proficiency for each analyst. Up-to-date training records of courses in ethical and legal responsibilities, including potential punishments and penalties for violations, are kept in the QA department.

Quality Manual Signature Page

This is to certify that I have read and understood Eurofins Eaton Analytical's Quality Manual.

I further certify that I will comply with the laboratory procedures and practices described in the manual for the generation of high quality data.

If you know any deviations in the laboratory practices, please notify your supervisor or Quality Manager to evaluate if the said deviation adheres to good laboratory practices and affects data quality.

If you find errors in any section applicable to you, please notify your supervisor or Quality Manager to correct them appropriately. The Quality Manual will be revised annually to reflect current laboratory practices.

Laboratory SOP and Method Reference Training Documentation

I certify that I have read, understood and agreed to perform the techniques and procedures, including instrument calibration procedures if applicable, stated in the most recent version of the approved test method and the laboratory standard operating procedure.

Table 4-1 List of SOPs

SOP No.	Analytes	Method	Issue Date	Revision No.
Wet Chem 01	Cyanide Analysis by Ion Selective Electrode (ISE)	EPA 9012B/ SM 4500-CN F,G	4/13/2012	13.0
Wet Chem 02	Fluoride by Ion Selective Electrode	EPA 9214/ SM 4500-F B,C	11/21/2012	13.0
Wet Chem 03	Alkalinity	SM 2320B	6/7/2013	12.0
Wet Chem 04	Total Dissolved Solids (TDS) in water	SM 2540C	11/20/2012	17.0
Wet Chem 05	Total Suspended Solids (TSS) in water	SM 2540D	6/12/2013	8.0
Wet Chem 06	Turbidity - Nephelometric	EPA 180.1/ SM 2130B	6/10/2013	10.0
Wet Chem 07	Total Solids (TS) in Aqueous Sample	SM 2540B	6/12/2013	7.0
Wet Chem 09	Settleable Solids	SM 2540F	11/11/2011	6.0
Wet Chem 11	Color	SM 2120 B	11/11/2011	9.0
Wet Chem 12	Conductivity (EC)	EPA 120.1, 9050A/ SM 2510B	11/21/2012	11.0
Wet Chem 13	Cyanide (Reflux-Distillation) Midi Distillation	EPA 335.4	11/20/2012	11.0
Wet Chem 14	Orthophosphate, Total, Suspended and Dissolved	EPA 365.1/ SM 4500-P F	11/21/2012	8.0
Wet Chem 15	Odor	SM 2150	1/10/2012	9.0
Wet Chem 16	Determination of Perchlorate in Drinking Water using Ion Chromatography	EPA 314.0/ CADHS 300.0 Modified	11/21/2012	10.0
Wet Chem 17	Biochemical Oxygen Demand	SM 5210B	6/12/2013	15.0
Wet Chem 19	Phenolics and Phenolics-Low	EPA 420.1 / 420.4	9/3/2010	13.0
Wet Chem 21	Determination of Nitrate / Nitrite by Flow Injection Analysis	EPA 353.2	11/21/2012	12.0
Wet Chem 22	Total Kjedahl Nitrogen by Colorimetric Analysis follwing Semi-Automated Digestion	EPA 351.2	11/21/2012	12.0
Wet Chem 25	Determination of Anions and Inorganic Disinfectant By-Products by Ion Chromatography	EPA 300.0, 9056	11/21/2012	20.0
Wet Chem 26	Total Volatile Solids/Volatile Suspended Solids in Liquid	EPA 160.4	3/26/2012	8.0
Wet Chem 27	Ammonia as Nitrogen by Rapid Flow Analyzer (RFA)	EPA 350.1/ SM 4500-NH3 D,H	11/28/2012	12.0
Wet Chem 28	pH Value	EPA 9040B, 150.1/ SM 4500-H+B	11/21/2012	7.0
Wet Chem 31	Surfactants, Anionic (MBAS)	SM 5540 C	6/12/2013	8.0
Wet Chem 32	Total Organic Carbon and Dissolved Organic Carbon by UV/ Persulfate Oxidation	EPA 9060A/ SM 5310C	11/21/2012	13.0
Wet Chem 34	Analytical method for Ultraviolet Absorption of Organic constituents at 254 nm	SM 5910B	1/10/2012	6.0
Wet Chem 35	Sulfide Determination (Methylene Blue)	EPA 9030B, 9034/ SM 4500-S2-D	8/20/2010	7.0
Wet Chem 36	Chemical Oxygen Demand (COD)	EPA 410.4/ SM 5220D	11/21/2012	11.0
Wet Chem 37	Determination of Total Cyanide by Semi-Automated Colorimetry	EPA 335.4	4/9/2012	12.0
Wet Chem 38	Determination of Total Phosphate by Flow Injection Analysis Colorimetry	EPA 365.1/ SM 4500-PF	1/18/2012	7.0
Wet Chem 39	Langelier Index by Calculation	SM 2330B	11/21/2012	4.0
Wet Chem 40	Determination of Inorganic Anions and trace Bromate in Drinking Water using Ion Chromatography by the addition of a Post-column reagent and Absorbance Detector in Series with an Electrochemical Detector	EPA 300.1/EPA 317.0	2/8/2013	22.0
Wet Chem 42	Dissolved Organic Halogen: Adsorption-Pyrolysis-Titrimetric Method	SM 5320B	8/20/2010	13.0

SOP No.	Analytes	Method	Issue Date	Revision No.
Wet Chem 43	Dissolved Oxygen, Membrane Electrode	SM 4500 OG	11/11/2011	4.0
Wet Chem 48	Determination of Low Level Perchlorate in Drinking Water using Ion Chromatography	EPA 314.0	11/28/2012	5.0
Wet Chem 49	Determination of Dissolved Hexavalent Chromium in Drinking Water, Groundwater, and Industrial Wastewater Effluents by IC	EPA 218.6	11/28/2012	5.0
Wet Chem 53	A Simplified and Rapid Method for Biodegradable Dissolved Organic Carbon Measurement (BDOC)	N/A	11/11/2011	3.0
Wet Chem 54	Determination of EDTA & NTA in Water Using Ion Chromatography by the Addition of a Post-column Reagent and Absorbance Detector	Metrohm Method	7/7/2010	0.0
Wet Chem 55	Chlorate by 300.1	EPA 300.1	6/18/2013	4.0
Wet Chem 56	UCMR3 – Determination of Hexavalent Chromium in Drinking Water by Ion Chromatography with Post Column Derivatization and UV/VIS Detection	EPA 218.7	6/18/2013	4.0
Extract 03	Liquid - Solid Extraction	EPA 525.2	2/28/2013	16.0
Extract 04	Determination of Endothall in Drinking Water by Solid Phase Extraction	EPA 548.1	11/26/2012	12.0
Extract 05	Liquid-Solid Extraction of Diquat and Paraquat	EPA 549.2	11/26/2012	11.0
Extract 11	Extraction BNA Continuous Liquid-Liquid Extraction	EPA 8270 C	11/19/2012	13.0
Extract 16	Solid Phase Extraction of Phenols in Drinking Water	EPA 528	4/13/2012	3.0
Extract 17	Solid Phase Extraction of Explosives in Drinking Water	EPA 529	1/25/2012	2.0
Extract 18	Solid Phase Extraction of Selected Pesticides and Flame Retardants in Drinking Water	EPA 527	1/19/2012	4.0
Extract 19	Determination of Nitrosamines in Drinking Water by Solid Phase Extraction (SPE)	EPA 521	12/31/2012	3.0
Extract 20	Measurement of Chloroacetanilide and Other Acetamide Herbicide Degradates in Drinking Water by Solid Phase Extraction	EPA 535	12/31/2012	4.0
Extract 21	Determination of MCPA, MCPB and MCPP in Drinking Water by Solid Phase Extraction (SPE) Modified SM 555	EPA 555	4/13/2012	2.0
Extract 22	Liquid-Solid Extraction	EPA 526	7/31/2012	2.0
Extract 23	Determination of Phenylurea Compounds in Drinking Water by SPE	EPA 532	4/13/2012	2.0
Extract 24	EDC4 by Continuous Liquid-Liquid Extraction	EDC4	11/19/2012	3.0
Extract 25	Determination of Nitrosamines in Drinking Water by Liquid-Liquid Phase Extraction	EPA 521	11/19/2012	2.0
Extract 26	Extraction for Determination of 2,3,7,8-TCDD by Isotope Dilution in Drinking Water by Capillary Column Gas Chromatography with Large Volume Injection and Electron Ionization Tandem Mass Spectrometry (EI/MS/MS) Modified EPA 1613B	EPA 1613B	11/19/2012	2.0
Extract 27	Determination of 1,4-Dioxane in Drinking Water by Solid Phase Extraction	EPA 522	6/18/2013	4.0
GC 03	EDB, DBCP and 1,2,3-TCP in water by Microextraction and Gas Chromatography	EPA 504.1	11/26/2012	14.0
GC 08	Chlorination Disinfection Byproducts and Chlorinated Organic Solvents by Liquid-Lquid Extraction and Gas Chromatography with Electron-Capture Detection	EPA 551.1	11/21/2012	20.0
GC 09	Haloacetic Acids	SM 6251 B	11/26/2012	17.0
GC 16	1,2,-Dibromoethane & 1,2-Dibromo-3-Chloropropane by Microextraction & Gas Chromatography	EPA 8011	11/26/2012	7.0
GC 27	Free and Total Chlorine Analysis and Chloramine Calculation	SM 4500-Cl-G	2/2/2012	8.0
GC 29	Formation of Trihalomethanes and other disinfection by-products. Modified Standard Method 5710 B and 5710D	SM 5710 B and SM 5710 D	8/20/2010	3.0
GC 33	Chlorine Dioxide Analysis	SM 4500-CLO2-D	2/2/2012	3.0
GC 34	Chlorinated Pesticides and PCBs	EPA 505	5/28/2013	13.0
GC 35	Chlorinated Acids in Drinking Water by Liquid-Liquid Extraction, Derivatization and Gas Chromatograph with Electron Capture Detection	EPA 515.4	11/26/2012	10.0

SOP No.	Analytes	Method	Issue Date	Revision No.
GC 36	Chlorine Demand. Modified Standard Method 2350B	SM 2350B	2/2/2012	2.0
GC 37	Aldehydes	EPA 556	2/11/2010	0.0
GC 38	Haloacetic Acids	EPA 552.3 Rev. 1.0	5/3/2010	0.0
GCMS 01	Volatile Organic Compounds in Drinking Water by GC/MS	EPA 524.2 (Modified)	6/7/2013	24.0
GCMS 01a	Determination of 1,2,3 Trichloropropane (TCP) in Drinking Water by Purge and Trap GC/MS in SIM Mode	EPA 524.2 (Modified)	11/21/2012	5.0
GCMS 01b	Determination of tert-Butanol, Epichlorohydrin, 1,2-Dichloropropane, 1,2,3-Trichloropropane and Cyanogen Chloride in Drinking Water by purge and trap GC/MS in SIM mode	EPA 524.2 (Modified)	11/21/2012	3.0
GCMS 02	Determination of Semivolatile Organic Compounds in Drinking Water by Gas Chromatography/Mass Spectrometry	EPA 525.2	6/7/2013	27.0
GCMS 03	Endothall Analysis by GCMS	EPA 548.1	6/7/2013	15.0
GCMS 04	Volatile Organic Compounds in Aqueous Matrix by GC/MS	EPA 624 (Modified)	10/24/2012	11.0
GCMS 05	Analysis of Semivolatile Organic Compounds by GCMS	EPA 625	9/16/2010	10.0
GCMS 07	Volatile Organic Compounds in Water by GC/MS	EPA 8260 B	11/21/2012	11.0
GCMS 08	Analysis of Semivolatile Organic Compounds by GCMS	EPA 8270 C	4/10/2012	9.0
GCMS 15	Determination of Selected Semivolatile Organic Compounds in Drinking Water by Solid Phase Extractions and Capillary Column GCMS	EPA 526	9/16/2010	5.0
GCMS 16	Determination of Phenols in Drinking Water by Capillary Column GCMS	EPA 528 Soda	8/20/2010	4.0
GCMS 17	Taste and Odor Analytes by Solid Phase Micro-Extraction and GCMS	SM 6040D	2/1/2013	5.0
GCMS 20	Determination of Nitrosamines in Drinking Water by Capillary Column GC with Large Volume Injection and Chemical Ionization Trap Mass Spectrometry	EPA 521	3/21/2013	4.0
GCMS 21	Determination of Explosives and Related Compounds in Drinking Water by Solid Phase Extractions and Capillary Column GCMS	EPA 529	9/3/2010	3.0
GCMS 22	Determination of Endocrine Disruptor Chemicals in Wastewater by GCMS Method 4	EDC 4SCR	9/16/2010	3.0
GCMS 23	Determination of Selected Pesticides and Flame Retardants in Drinking Water by Solid Phase Extraction and Capillary Column Gas Chromatography/Mass Spectrometry (GC/MS)	EPA 527	9/3/2010	3.0
GCMS 24	Determination of 2,3,7,8-TCDD in Drinking Water by Capillary Column Gas Chromatography with Large Volume Injection and Electron Ionization Tandem Mass Spectrometry (EI/MS/MS)	EPA 1613B (Modified)	6/7/2013	2.0
GCMS 25	Determination of Galaxolide in Wastewater Using USGS Endocrine Disrupter Chemicals Method 4 by Gas Chromatograph/Tandem Mass Spectrometry	Galaxolide	4/23/2010	0.0
GCMS 26	Determination of 1,4-Dioxane in Drinking Water by Solid Phase Extraction with GCMS with Selected Ion Monitoring (SIM)	EPA 522	6/18/2013	4.0
GCMS 27	Volatile Organic Compounds in Drinking Water by GC/MS	EPA 524.3	6/18/2013	4.0
HPLC 02	Glyphosate Analysis in Drinking Water by High Performance Liquid Chromatography (HPLC)	EPA 547	11/21/2012	15.0
HPLC 03	Diquat and Paraquat Analysis in Drinking Water by HPLC	EPA549.2	6/7/2013	16.0
HPLC 05	Carbamates Analysis in Drinking Water by HPLC with post column derivatization	EPA 531.2	11/26/2012	7.0
HPLC 06	Determination of Phenylurea Compounds in Drinking water by Solid Phase Extraction and HPLC with UV Detection	EPA 532	11/21/2012	4.0
HPLC 07/ LCMS 01	Determination of Perchlorate in Drinking Water by Liquid Chromatography/Electrospray Ionization Tandem Mass Spectrometry	EPA 331	2/8/2013	4.0
HPLC 08	Analysis of MCPA, MCPB and MCPP in Drinking Water by HPLC	EPA 555	11/15/2012	4.0
HPLC 09	Measurement of Chloroacetanilide and other Acetamide Herbicide Degradates in Drinking Water by Solid Phase Extraction (SPE) and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)	EPA 535	8/19/2010	4.0
HPLC 10/ LCMS 02	Determination of Acrylamide in Drinking Water by Liquid Chromatography Electrospray Ionization/Mass Spectrometry	Acrylamide	8/27/2010	1.0
HPLC 11/ LCMS 03	Determination of Emerging Organic Pollutants in Environmental Matrices by Liquid Chromatography Mass Spectrometry in Tandem Analysis (LC/MS/MS)	EDC 2	8/27/2010	1.0

SOP No.	Analytes	Method	Issue Date	Revision No.
HPLC 12/ LCMS 04	Determination of Perfluorinated Pollutants in Environmental Matrices by Online Solid-Phase Extraction (SPE) coupled with HPLC/MS in Tandem	PFC	4/2/2010	4.0
HPLC 13/ LCMS 05	Determination of Selected Perfluorinated Alkyl Acids in Drinking Water by Solid Phase Extraction and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)	EPA 537	11/15/2012	5.0
HPLC 14/ LCMS 06	The Determination of Personal Care Products, Pharmaceutical (PPCP) and Endocrine Disrupters Compounds (EDC), Herbicide and Degradates in Environmental Matrices by Online Solid-Phase Extraction Coupled with High-Performance Liquid Chromatography/Mass Spectrometry in Tandem	PPCP	4/23/2010	0.0
HPLC 16/LCMS 07	Determination of Hormones in Drinking Water by Solid Phase Extraction (SPE) and Liquid Chromatography Electrospray Ionization Tandem Mass Spectrometry (LC-ESI-MS/MS)	EPA 539	6/18/2013	4.0
LCMS 08	Determination of Iodide and Iodate in Drinking Water by Liquid Chromatography/Electrospray Ionization Tandem Mass Spectrometry			
LCMS 11	Determination of Selected Perfluorinated Alkyl Acids in Drinking Water by Solid Phase Extraction and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)	UCMR3 537	6/18/2013	0.0
Met 01	Analysis of Trace Elements by ICP Emission Spectroscopy	ICP, EPA 200.7, 6010B, 6020A	11/19/2012	20.0
Met 02	Trace Metals by ICP/MS	ICP/MS, EPA 200.8, 6020A	6/7/2013	30.0
Met 04a	Mercury by Cold Vapor Atomic Absorption	SW846 Method 7470, EPA 245.1, 7470A	11/19/2012	19.0
Met 19	Hexavalent Chromium, Colorimetric Method	EPA 7196 A / SM 3500 CR-B /SM3500 CR -D	11/19/2012	11.0

CALIFORNIA STATE

ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM BRANCH

CERTIFICATE OF NELAP ACCREDITATION

Is hereby granted to

Eurofins Eaton Analytical, Inc. (former M.W.H.)

750 Royal Oaks Drive, Suite 100
Monrovia, CA 91016

Scope of the Certificate is limited to the
"NELAP Fields of Accreditation"
which accompany this Certificate.

Continued accredited status depends on successful
ongoing participation in the program.

This Certificate is granted in accordance with provisions of
Section 100825, et seq. of the Health and Safety Code.

Certificate No.: **01114CA**

Expiration Date: **1/31/2014**

Effective Date: **2/1/2013**

Richmond, California
subject to forfeiture or revocation

David Mazzera, Ph.D., Assistant Division Chief
Division of Drinking Water and Environmental Management

Ed Wilson
Eurofins Eaton Analytical, Inc. (former M.W.H.)
750 Royal Oaks Drive, Suite 100
Monrovia, CA 91016

Dear Ed Wilson:

Certificate No. 01114CA

This is to advise you that the laboratory named above has been accredited under National Environmental Laboratory Accreditation Program (NELAP) as an environmental testing laboratory pursuant to the provisions of the Health and Safety Code (HSC), Division 101, Part 1, Chapter 4, Section 100825, *et seq.*

The Fields of Accreditation for which this laboratory has been accredited are enclosed. The certificate shall remain in effect until **January 31, 2014** unless revoked by California Environmental Laboratory Accreditation Program Branch (ELAPB) or withdrawn at your written request. To maintain accreditation, the laboratory shall comply with the National Environmental Laboratory Accreditation Conference (NELAC) Standards and all associated California ELAPB regulations and statutes.

The application for renewal of this certificate must be received before the expiration date of this certificate to remain in force according to the HSC 100847(a).

Please note that your laboratory is required to notify California ELAPB of any major changes in key accreditation criteria within 30 calendar days of the change. This written notification includes, but is not limited to, changes in ownership, location, key personnel, and major instrumentation (HSC 100847(b), (c), (d), and NELAC Standard Section 4.3.2). The certificate must be returned to California ELAPB upon loss of accredited status.

Your continued cooperation with the above requirements is essential for maintaining the high quality of the data produced by environmental laboratories accredited by the State of California.

If you have any questions, please contact Bill Walker at (818) 551-2012.

Sincerely,

for
David Mazzera, Ph.D., Assistant Division Chief
Division of Drinking Water and Environmental Management

Enclosure

CDPH
California Department of Public Health

CALIFORNIA STATE

ENVIRONMENTAL LABORATORY ACCREDITATION PROGRAM BRANCH

CERTIFICATE OF ENVIRONMENTAL ACCREDITATION

Is hereby granted to

MWH LABORATORIES, A DIVISION OF MWH AMERICAS, INC.

750 ROYAL OAKS DRIVE, SUITE 100
MONROVIA, CA 91016

Scope of the certificate is limited to the
"Fields of Testing"
which accompany this Certificate.

Continued accredited status depends on successful completion of on-site, proficiency testing studies, and payment of applicable fees.

This Certificate is granted in accordance with provisions of Section 100825, et seq. of the Health and Safety Code.

Certificate No.: **1422**
Expiration Date: **01/31/2013**
Effective Date: **02/01/2011**

Richmond, California
subject to forfeiture or revocation

George C. Kulasingam

January [illegible], 2012

[illegible]

Dear [illegible]: Certificate No. [illegible]

This is to advise you that the laboratory named above has been certified as an environmental [illegible]

[illegible] "Fields of Testing". The certificate shall remain in effect until January 31, 20[illegible] [illegible]

[illegible]

[illegible] quality of analysis in the Fields of Testing for which this laboratory has been granted a certificate; [illegible]

[illegible]

If you have any questions, please contact [illegible]

Sincerely,

[illegible]

Environmental Laboratory Accreditation Program Branch

MONROVIA, CA 91016

[redacted]

FACILITY SITE ADDRESS: 750 ROYAL OAKS DR # 100, MONROVIA, CA 91016

THIS PERMIT IS ISSUED FOR THE FOLLOWING PROGRAMS:

Administering Agency:	Program Description:
CITY OF MONROVIA	HAZARDOUS MATERIALS DISCLOSURE PROGRAM
LA COUNTY FIRE DEPARTMENT	HAZARDOUS WASTE GENERATOR PROGRAM
LA COUNTY FIRE DEPARTMENT	TIERED PERMIT - CONDITIONALLY EXEMPT (CE)

THIS PERMIT MUST BE CONSPICUOUSLY DISPLAYED AT THE FACILITY AT ALL TIMES.

ISSUED BY: Daryl L. Osby
County of Los Angeles Fire Chief

ISSUED ON: Nov 16, 2012

This permit is valid only for the above location and is subject to ALL REQUIRMENTS of State and Local Laws. The permit is non-transferrable and is void upon change in ownership or location.

5.0 QUALITY ASSURANCE OBJECTIVES

Before analytical data can be used, the quality of data produced by EEA is measured by the following characteristics: precision, accuracy, completeness, representativeness, comparability, timeliness, and documentation, used in the determination of the suitability of the data for a given purpose. EEA has set specific objectives for each of these characteristics as a means of meeting the data quality objectives of the client. A definition of each of the characteristics follows, along with the specific objectives for each of the characteristics.

Table 5-1 lists specific limit objectives for precision and accuracy for drinking water analyses.

Table 5-2 lists specific limit objectives for precision and accuracy for wastewater analyses.

Table 5-3 lists specific limit objectives for precision and accuracy for hazardous waste analyses.

Criteria for precision and accuracy included are only for representative reference methods. Criteria for the other methods and specific analytes can be found in relevant SOPs.

5.1. PRECISION

Analytical precision is an important component of overall data quality since it is a measure of how far an individual determination may be from the mean of replicate measurements (how well replicate analyses agree). If the precision of an analysis is poor, there is a good probability that the reported result will differ substantially from the true value even if there are no systematic errors leading to bias in the result. Precision is often directly related to concentration.

5.1.1. EEA uses Relative Percent Difference (RPD) to measure agreement between duplicate analyses. RPD is calculated as follows:

$$\mathbf{RPD} = \frac{(S-D)}{(S+D)/2} \times 100$$

where;

RPD	=	Relative Percent Difference
S	=	First Sample Value (original)
D	=	Second Sample Value (duplicate)

5.1.2. The precision of a method is expressed as the Relative Standard Deviation (RSD) of the percent recoveries. Percent RSD (%RSD) is calculated as follows:

$$\%RSD = \frac{S}{X_{avg}} \times 100$$

where:

X_{avg} = the arithmetic mean of the recovery values, and

$$S = \sqrt{\Sigma \frac{(X_i - X)^2}{n-1}}$$

where:

S	=	Standard Deviation
X_i	=	the individual recovery values
X	=	the arithmetic mean of the recovery values
n	=	the number of determinations

5.1.3. To assess precision in the laboratory, EEA uses the following:

- Duplicate Samples
- Duplicate Matrix Spikes
- Duplicate Laboratory Control Samples
- Control Charts

5.2. ACCURACY

Accuracy is the agreement between an experimentally determined value and the accepted reference value (deviation of the analytical value from the "true or known value). Analytical accuracy is a measure of analytical bias due to systematic errors. A measure of this bias along with a measure of the precision will provide the overall accuracy of the results.

The true value for field samples are never known, so accuracy measurements are made on the analysis of QC samples analyzed with field samples. The primary QC tools for assessing accuracy are control standards (LCSs), matrix spikes and spike duplicates (MS/MSD), and surrogate spikes.

5.2.1. Spike recoveries are calculated as follows:

$$\%R = \frac{SSR - SR}{SA} \times 100$$

Where;	%R	=	percent spike recovery
	SSR	=	spiked sample result
	SR	=	sample result
	SA	=	spike amount added

5.2.2. For Laboratory Control Samples, percent recovery (%R) is calculated as follows:

$$\%R = \frac{\text{found concentration}}{\text{true concentration}} \times 100$$

5.2.3. Accuracy is monitored for nearly all methods by percent recoveries of the LCSs and plotted on control charts. The mean recovery ± 2 standard deviations are the warning limits, and the mean recovery ± 3 standard deviations are the control limits. In the event that the method has no acceptance criteria, control charts are reviewed and evaluated to establish internal limits or guidelines [TNI-EL-V1M4-2009-1.7.4.2.a].

To assess accuracy, EEA uses the following:

- MRL Checks
- Laboratory Control Samples
- Matrix Spikes
- Certified Reference Materials
- Blind QC Samples
- Control Charts

5.3. REPRESENTATIVENESS/SAMPLING OF SUB-ALIQUOT

All sample aliquots, which are analyzed, must be representative of the bulk sample from which they are taken [TNI-EL-V1M2-2009-5.7.1][ISO/IEC 17025:2005(E)-5.7.1]. Representativeness is easily achieved for aqueous samples free of suspended material. Obtaining a representative sample is a more difficult task for soils and sludge.

Unless a sample is known to be non-randomly heterogeneous in its composition, the most appropriate manner of obtaining a representative aliquot for analysis is by simple random sampling after the material has been mixed as thoroughly as possible. Thorough mixing is acceptable for inorganic analyses, but any samples requiring volatile or semi-volatile organic analyses must be handled in a manner which minimizes loss of these volatile compounds from the sample.

Representativeness is also impacted by conditions of sample receipt. EEA documents all samples that do not meet acceptance criteria (TNI-EL-V1M2-2009-5.8.3) (ISO/IEC 17025:2005(E)-5.8.3).

The laboratory documents the sampling techniques of aliquots from a submitted sample in the method SOPs to ensure that representativeness of samples are obtained. (TNI-EL-V1M2-2009-5.7.1)(ISO/IEC 17025:2005(E)-5.7.1).

5.4. COMPARABILITY

The characteristic of comparability determines whether analytical conditions are uniform for each analytical run to insure that all of the reported data will be consistent. This requires temporal stability of analytical conditions within the laboratory.

To insure temporal stability, uniform analytical and quality control protocols will be closely adhered to for each analytical run. In addition, traceable standards are used as part of every analytical run. Every analyst is required to demonstrate his precision and accuracy for a particular analysis by analyzing four replicate matrix spiked samples. All newly trained or backup analysts must demonstrate comparable precision and accuracy.

5.5. COMPLETENESS

The characteristic of completeness is a measure of the percentage of specified data which are valid. Valid data are obtained when samples are analyzed in accordance with the quality control procedures outlined in this manual and none of the quality control criteria is exceeded.

Sample data which does not meet the specified quality control criteria will automatically be reanalyzed if sufficient quantity of sample is available and analytical holding times have not been exceeded. The laboratory strives for a completeness percentage of 100%.

5.6. TIMELINESS

EPA guidelines require that samples be analyzed for constituents within specified holding times. These holding times represent a compromise between allowance of a realistic time to perform the analysis and minimization of elapsed time to insure sample integrity.

EEA has adopted a computerized sample tracking system and supervisory review process to insure that samples are scheduled for extraction and analysis within the EPA holding times. In the unforeseen circumstance of instrument performance problems, EEA will do everything possible to meet EPA holding times without compromising the quality of the reported data. The client is notified if a holding time is exceeded.

5.7. DOCUMENTATION

Proper documentation is a vital component in supporting the integrity of analytical results. All of the proceeding quality control components will not support reported data unless they have been fully documented for subsequent review. EEA maintains documentation of sample handling, chain of custody (if applicable), analytical procedures, raw and calculated data, supporting chromatograms, quality control data, and final reports. Please see section 14 for data reduction, validation, and reporting procedures.

NOTE: When the method does not specify the Acceptance Limit, recovery limits are based on control charts.

6.0 QUALITY OF TEST RESULTS

6.1. ESSENTIAL QUALITY CONTROL PROCEDURES

The laboratory has established a quality control program that is designed to provide two different types of information about a particular analysis. The ability to confidently evaluate laboratory performance in terms of analytical bias and precision is accomplished through the use of both laboratory control samples (LCS), in the absence of sample matrix effects, and the traditional approach of using matrix spikes and duplicate (MS/MSD) analyses.

The quality control program implemented at EEA recognizes the problems associated with the use of matrix spikes and duplicates, and thus decisions regarding method data quality, when matrix effects are present, are made using data obtained from all control samples. The types and frequencies of control samples used at EEA are summarized below. Method Acceptance Limits are used to validate analytical results for each test. When method reference does not specify acceptance limits for the QC type, control limits are calculated and used as acceptance limits. The Control limits are recalculated at least annually for drinking water and waste water matrices and every 6 months for Hazardous Waste matrix. (See relevant SOP for the current control limits).

6.1.1. NEGATIVE CONTROL

6.1.1.1. Method Blanks

A method blank consists of laboratory pure water containing all of the reagents utilized in the analytical procedure. The method blank is prepared in the same manner as a sample and is processed through all of the analytical steps. All reagents are dated upon receipt in the laboratory and each new lot of reagents is checked by performance of method blanks.

Method blanks are processed along with the associated samples (minimum one MB per prep batch or analytical batch of ≤ 20 samples) performed to determine whether there is reagent contamination or instrument contamination due to sample carryover. The method blanks must remain below the MRL for each analyte of interest. Some analyses (see specific SOPs) have a more stringent requirement (e.g. < ½ or < 1/3 MRL). If samples require a preparatory procedure such as a digestion or extraction prior to analysis, a method blank must be carried through the entire process and analyzed in addition to the instrumental calibration blanks.

When a blank is determined to be contaminated, the cause must be investigated and measures taken to minimize or eliminate the problem. Samples associated with a contaminated blank shall be evaluated as to the best corrective action for the samples (e.g. reprocessing or data qualifying codes). In all cases the corrective action must be documented [TNI-EL-V1M4-2009-1.7.4.1.c].

Method blanks are analyzed as part of the initial or daily calibration process (calibration blanks) and after every 20 samples for each matrix type to monitor the overall procedural blank as well as the purity of the reagents. If analyte in method blanks is >MRL and is >1/10 of amount measured in sample and if blank contamination affects samples or individual data, quality, objectives, the problem is eliminated and reprocessed or affected samples appropriately qualified.

6.1.1.2. **Travel Blanks**

The trip blank is required to be analyzed in the event of any detects in the associated field samples. For example, both methods 504.1 and 524.2 for volatiles determination require a trip blank with each set of samples.

When running method 525.2 for phthalates determination for compliance monitoring purposes, the laboratory runs a trip blank if any of the samples are found positive for phthalates. This is necessary to show that samples were not contaminated from bottle caps, the HCl used for preservation, or the latex gloves worn during sampling. If the samples show the presence of phthalates and there was no trip blank with the set of samples then subsequent resamples from the site must be accompanied by a trip blank. If the samples are not to be analyzed for phthalates, the laboratory does not need to run a trip blank.

If a client has submitted a trip blank and wishes it to be analyzed automatically, the sample is logged in with the appropriate tests and with the log-in ID "Trip Blank" so that analysts will know to analyze and report them.

If a trip blank is submitted and is only to be analyzed in the event of hits, the sample is logged in with an ID of "Trip Blank-Hold."

For the analysis of ethylene dibromide and dibromochloropropane by Method 504.1 and phthalates by method 525.2, the analyst and supervisor ensure that if hits are detected in the associated samples, the trip blank is analyzed and reported within holding times.

Because of the relatively short holding times for VOAs by Method 524.2 and 504.1, the trip blanks are usually analyzed (unless specified by client) whether or not there are hits in the associated sample. In this way, Trip Blanks are always analyzed within holding times.

If there is adequate holding time remaining the analyst may elect to not analyze the trip blank. However in this case, the data should be reduced immediately and if there are hits, the sample should be analyzed on the next run, still within holding time.

In the event that no hits are present in the associated client samples the analyst and supervisor enter NA for the trip blank and preferably place a comment on the sample “not analyzed, no hits in field samples".

In the event that an analyte is detected in the trip blank, the analyst gets the associated stationary blank from shipping, if available, and runs that immediately to confirm that the hits are not due to lab contamination when the blank was prepared. The information to associate the proper trip blank to the sample(s) is be found on the sample bottle label, through the LIMS numbering system, and/or on the COC.

6.1.1.3. **Field Blanks**

Field blanks are used to identify contamination that may have occurred during the sample collection process. Empty containers with the applicable preservatives are sent to the field and filled at the sampling location at the time of sampling from a bottle with analyte-free water that was prepared at the laboratory as per client's request. The empty sample bottle and field blank sample bottle will be provided.

6.1.1.4. **Sample Blanks**

Sample blanks are used with spectrophotometric methods where sample characteristics such as color may give erroneous results. The absorbance of a sample is measured before and after the color development process. The absorbance before is subtracted from the absorbance after to give the true absorbance. Sample blanks are analyzed on an as-needed basis.

6.1.1.5. **Calibration Blanks (CB)**

For non-chromatographic analysis, calibration blanks are prepared along with the calibration standards and differ from the standards only in that the calibration blank does not contain any of the analyte(s) of interest. The calibration blank, by definition, provides the "zero point" in the calibration curve.

6.1.2. **Positive Control**

6.1.2.1. **Laboratory Control Sample (LCS)/Laboratory Fortified Blank (LFB)**

The LCS is used to evaluate the performance of the total analytical system, including all preparation and analysis [TNI-EL-V1M4-2009-1.7.3.2.1].

Laboratory control samples (LCSs) are defined as an interference free matrix spiked with a particular set of method-specific target compounds at a level 5-10 times above the minimum reporting limit. The matrix used to prepare aqueous LCS samples is laboratory reagent water (deionized water - carbon-filtered for organic analyses) and all method preservatives. In some cases LCS must be from a second or independent source, but other methods allow for the use of same sources. LCS is run at a frequency of one LCS per prep batch or analytical batch of $\leq$ 20 samples.

The purpose of the LCS matrix is not to duplicate the sample matrix, but more importantly to provide a consistent matrix with which baseline performance data for an analysis can be generated. This feature of the LCS provides one of the most significant advantages over the use of matrix spikes and spike duplicates. The variable matrix interferences inherent to matrix spikes and spike duplicates are manifested in the extremely wide control limits presented in the methods. This variability results in a large relative standard deviation in the data used to calculate the control limits which forces the control limits to become wider. The control of this variability significantly reduces the relative standard deviation of the data and results in control limits that are representative of laboratory precision alone.

6.1.2.2. **Matrix Spike and Matrix Spike Duplicate Samples (MS/MSD)**

MS/MSD samples are defined as a sample matrix spiked with a particular set of method-specific target compounds at a level 5-10 times above the minimum reporting limit. Samples are generally divided into two types of matrices, aqueous and non-aqueous.

Matrix spikes and spike duplicates are prepared using a sample matrix that is representative of the sample type being analyzed for a particular method. Frequency of the analysis of matrix spikes is as per method specifications or as per contract review.

6.1.2.3. **LCS and MS/MSD Concentration Levels**

When the method reference does not specify the LCS and MS/MSD concentration, the following criteria (in order of descending preference) are to be applied when determining the appropriate concentration of any particular analyte in the designated control sample:

6.1.2.3.1. If no MCL exists, or the MCL represents an impractical level relative to MDL or calibration range, the selected level should be set at the corresponding level used in the EPA's reference methods.

6.1.2.3.2. The level selected should be equal to any existing federal maximum contaminant level (MCL). This may not always be practical (as in the case of thallium [Tl]) when the MCL is too close to our actual MRL to yield consistent accuracy and precision.

6.1.2.3.3. If there is no EPA protocol for a particular method, or this level is inappropriate for the method, then the selected level should be near the midpoint of the calibration range. Optimally, this would be equivalent to the MCL, unless the calibration range spans more than 2 orders of magnitude.

6.1.2.3.4. If the calibration range spans 2 or more orders of magnitude, the selected level should be set at approximately 10 times the MRL for each analyte.

In some cases multiple levels (MRL, midpoint, high) are used to monitor control throughout the calibration range.

6.1.2.4. **Selection of Spike Analytes**

Any analyte reported must be included in the LCS and MS spiked sample for drinking water matrix samples. The selection of specific analytes to be spiked should be based on the following scheme:

6.1.2.4.1. If there are regulatory or method specific monitoring requirements for any of the target compounds, these compounds should be included.

6.1.2.4.2. If there are no regulatory or method specific monitoring requirements or additional analytes required to meet the absolute number to be included in the subset, follow TNI-EL-V1M4-2009-1.7.3.2.3 requirements for LCS spiking composition and TNI-EL-V1M4- 2009-1.7.3.3.1 for MS spiking composition.

6.1.2.4.3. As per the TNI Standard, for those test methods that have extremely long lists of analytes, a representative number may be chosen. The analytes selected should be representative of all analytes reported. The following criteria shall be used for determining the minimum number of analytes to be spiked for LCS and MS. However, the laboratory shall ensure that all targeted components are included in the spike mixture over a 2-year period. This can be applied for non-compliance samples, or other non-drinking water matrix samples.

- For methods that include 1-10 targets, spike all components;
- For methods that include 11-20 targets, spike at least 10 or 80%, whichever is greater;
- For methods with more than 20 targets, spike at least 16 components.

6.1.2.4.4. If neither of the above criteria apply, then the analytes should be selected for the subset so that all the different classes of compounds in the list of target compounds for the method are represented.

6.1.2.4.5. Any unique, method-specific problem analyte or element (such as potential loss of a particular analyte during extraction, digestion, or cleanup step or an element subject to severe inter-element interference on the ICP) should be represented in the subset.

6.1.2.4.6. In the absence of specified spiking components, for those components that interfere with an accurate assessment such as spiking simultaneously with technical chlordane, toxaphene and PCBs, the spike chosen represents the chemistries and elution patterns of the components to be reported. (TNI-EL-V1M4- 2009-1.7.3)

6.1.2.5. **Sample Preparation of LCS/LFB and MS/MSD**

The intent of this program is to set our control sample analytes and concentration levels such that a single concentrated stock mix is (1) independently prepared (preferably from different neat materials) from calibration stock solutions, and (2) can be used to prepare LCS samples as well as MS/MSD samples for both aqueous and non-aqueous environmental samples.

The ratio of spiked concentrate to sample aliquot used to prepare MS/MSD samples must be 1 to 10%, depending on the method specifications. In the case of matrix spikes, this practice ensures that we are not diluting the environmental sample to such an extent that we are diluting out any matrix interferences. The purpose of the matrix spike is to provide information regarding the ability to recover an analyte from a particular matrix.

6.1.2.5.1. **Stock Source of LCS/LFB and MS/MSD**

In order to serve its purpose as an external verification (reference) of the calibration, it is essential that the stock solutions used to prepare LCS and matrix spike samples be prepared independently of calibration stocks unless a method specifies a contrary approach. In the organics area, there is a lack of independent sources from which reference materials are obtained but the stock solutions should be prepared independently although they may share a common source.

The source of control sample reference materials should be selected in the following order of preference:

6.1.2.5.1.1. The neat compound must be prepared from either a completely independent sources. For example, a 1000-mg/L stock As solution obtained from Fisher is used to prepare As calibration standards, while a 1000 mg/L stock As solution obtained from Spex is used to prepare the control sample concentrate.

6.1.2.5.1.2. If a completely independent source cannot be obtained, the same vendor may be used, but the solution shall be from a completely different lot (second lot).

6.1.2.5.1.3. If it is impossible to obtain the reference material from two independent sources, or from two different lots, then the material from a single source can be used provided that a different analyst than the one who prepared the calibration stock is responsible for preparing the control sample solution.

6.1.2.6. **Frequency of MS/MSD**

MS/MSD samples are run at a frequency of one pair for every sample batch of 20 or less of a similar matrix. In cases where there is insufficient sample to run a MS/MSD as well as the original, a pair of LCS samples may be substituted to fulfill this requirement. There is often insufficient sample for aqueous samples to have a MS/MSD set up due to the large volumes of sample required for analysis. EEA encourages clients who require precision and accuracy information based on a particular matrix to make arrangements to submit adequate sample volumes for this purpose. By supplying these samples, the client is able to obtain not only specific information regarding laboratory performance (from LCS sample data), but also a measure of the applicability of the sample matrix to the analytical method used (from the matrix spike and duplicate data). If the matrix spike is used in place of the LCS, the acceptance criteria must be as stringent as the LCS [TNI-EL-V1M4-2009-1.7.3.2.3].

6.1.2.7. **Frequency of LCS/LFB**

Laboratory control samples are analyzed throughout a run at a frequency of 5%-10% for environmental samples of a similar matrix. Bias information is provided based on recovery data for the LCS and precision information is available by comparing LCS sample results using a RPD calculation. The frequencies are consistent with the requirements of most methods referenced in Standard Methods, EPA Manual for Chemical Analysis of Water and Waste, 40 CFR 136 for the wastewater methods, and EPA Manual for the Certification of Laboratories Analyzing Drinking Water, 5th Edition. Additional measures of precision and bias are obtained from other control samples, as specified in the SOP's.

In order to ensure that some measure of analytical control is provided with each batch of samples going through a pre-analysis preparation step, an LCS is prepared with each set of 20 samples extracted or digested for these analyses. In each case, an LCS will be associated with each set of samples prepared, to allow documentation of control of the analytical procedures. Some methods require varying concentrations of LCS throughout a run.

6.1.2.7.1. Analyses with a preliminary treatment step (i.e. extraction or digestion):

6.1.2.7.1.1. LCS frequency is one for every 10 to 20 samples (see individual method SOPs) or at least one for every preparation batch of ≤ 20 samples.

6.1.2.7.1.2. MS/MSD or LCS pair (in cases where there is insufficient sample volume for a MS/MSD) is prepared for every sample batch of 20 samples or as per method specifications.

6.1.2.7.2. Analyses not requiring pretreatment:

6.1.2.7.2.1. A LCS must be run with each analytical run at a frequency of no less than one for every 10 or 20 samples (see individual method SOPs).

6.1.2.7.2.2. A MS/MSD or LCS pair must be run for every batch of 20 samples as defined in method specifications or TNI standards.

6.1.2.7.2.3. Any exceptions to this frequency on a given run must be documented on a corrective action form.

6.1.2.8. **Evaluation Criteria of MS/MSD**

MS acceptance criteria are compared to the acceptance criteria as published in the mandated test method if not specified in the method. Advisory limits for each method are established initially based on method validation data. Initial control limits are defined as the mean recovery (accuracy) ± 3 times the standard deviation obtained from the analysis of 4 (or more) replicates spiked at approximately 10x MRL during the method validation process. Warning limits are set as the mean recovery (accuracy) ±2 times the standard deviation.

Firm acceptance criteria, based upon actual laboratory data, are established once a minimum of 20 data points has been generated. These historical control limits are compared to any method specified or recommended limits to assess their feasibility. Control limits are re-calculated at least yearly to verify that there has been no significant change in performance.

Precision is determined as the relative percent difference (RPD) between LCS pairs or MS/MSD samples. By linking a LCS or MS/MSD pair to each batch of 20 environmental samples, it is possible to link a measure of analytical precision (and two measures of analytical accuracy) to each environmental sample analyzed.

Precision control limits for some analytes have been adopted from the EPA CLP program where they exist, otherwise, control limits are set after the analysis of 20 MS/MSD or LCS pairs of samples (40 control samples). Control limits are set as the mean ± 3 standard deviations of the RPD from the 20-30 "pairs", with warning limits set at the mean ± 2 standard deviations. Until such time as 20-30 data points have been accumulated, interim acceptance criteria should be set as 3 times the standard deviations of the RPD obtained during the method validation process.

Whenever MS/MSD or LCS pairs do not meet these limits, an analysis may have a potential problem. Samples with failing LCS shall be reprocessed and reanalyzed or data reported with data qualifying codes. The source of any problems must be investigated and documented by preparing a corrective action or procedural variance report.

For drinking water method, when there is no method specification, the spike level should not be less than the concentration of the sample selected for fortification unless specified by the method. If the sample concentration is unknown or less than detectable, the analyst should choose an appropriate concentration. If the spike level is less than the concentration of the sample selected, the spike recovery value is unusable since the analyte concentration in the sample is disproportionate to the spike level.

6.1.2.9. Evaluation Criteria of LCS/LFB – Marginal Exceedances

If a large number of analytes are in the LCS, it becomes statistically likely that a few will be outside control limits. This may not indicate that the system is out of control, therefore corrective action may not be necessary. Upper and lower marginal exceedance (ME) limits can be established to determine when corrective action is necessary. A ME is defined as being beyond the LCS control limit (3 standard deviations), but within the ME limits. ME limits are between 3 and 4 standard deviations around the mean.

The number of allowable marginal exceedances is based on the number of analytes in the LCS. If more analytes exceed the LCS control limits than is allowed, or if any one analyte exceeds the ME limits, the LCS fails and corrective action is necessary. This marginal exceedance approach is relevant for methods with long lists of analytes. It will not apply to target analyte lists with fewer than 11 analytes.

The number of allowable marginal exceedances is as follows [TNI-EL-V1M4-2009-1.7.4.2]:

- >90 analytes in LCS, 5 analytes allowed in ME of the LCS control limit;
- 71 – 90 analytes in LCS, 4 analytes allowed in ME of the LCS control limit;
- 51 – 70 analytes in LCS, 3 analytes allowed in ME of the LCS control limit;
- 31 – 50 analytes in LCS, 2 analytes allowed in ME of the LCS control limit;
- 11 – 30 analytes in LCS, 1 analytes allowed in ME of the LCS control limit;
- < 11 analytes in LCS, no analytes allowed in ME of the LCS control limit.

Marginal exceedances must be random. If the same analyte exceeds the LCS control limit repeatedly, it is an indication of a systematic problem. The source of the error must be located and corrective action taken.

6.2. Sample Specific Controls

6.2.1. Internal and Surrogate Standards

Internal standards are run with GC/MS, GC, and HPLC analyses to monitor the efficiency of the analytical procedure for each sample matrix encountered and to monitor retention time shifts and the efficiency of the auto-sampler injection. Surrogate standards are run with GC/MS, GC, and HPLC analyses to monitor the efficiency of the extraction for each sample matrix encountered. When there are no established criteria for surrogates from the method, the lab determines internal limits through control charts.

Control limits are re-established annually for surrogates based on historical laboratory data from environmental sample matrices. Internal and surrogate standards are added to each sample analyzed by EPA Methods as recommended and run in accordance with the method procedures. For references to specific compounds used for internal and surrogate standards please reference the SOP.

Current surrogate acceptance limits may be found in Table 6-1.

6.2.2. **Spikes – Recoveries, RPDs**

Spiked sample analyses (MS/MSD) are performed to evaluate the effect of the sample matrix on the analytical methodology. A known amount of the analyte(s) of interest is added to an aliquot of sample, which is then analyzed along with the unspiked sample. Spiked samples are prepared and subjected to the same process as the original sample. Spike recoveries are calculated, and used to determine whether the sample matrix interferes with the method.

Spike recoveries are calculated as follows:

$$\%R = \frac{SSR - SR}{SA} \times 100$$

Where;

%R	=	percent spike recovery
SSR	=	spiked sample result (corrected for any dilution in spiking)
SR	=	sample result
SA	=	spike amount added

The Laboratory documents the percent (%) recoveries and %RPD for MS/MSD samples [TNI-EL-V1M4-2009-1.7.4.3.a].

6.2.3. **Duplicates, Duplicate Spikes**

Duplicate analysis of a sample has traditionally been used to obtain a measure of analytical precision in the form of a relative percent difference (RPD) calculation between the two values. EEA routinely will analyze duplicate spiked control samples, MS/MSD to meet specific client's QC requirements such as Arizona.

Since no precision information is obtained when either or both of the duplicates have analyte concentrations below the MRL, duplicate analysis of the spiked samples makes the most sense. While still subject to interference problems the advantage of duplicate matrix spikes is clearly the ability to obtain calculated RPD values specific for a particular sample matrix. Clients are encouraged to submit sufficient sample for the analysis of MS/MSD samples by specific request when a RPD value for their particular matrix is desirable.

Ongoing analytical precision is evaluated by tracking the difference between the MS/MSD (or LCS pairs) analyzed with each batch of 20 samples. These differences are compared to control limits established for each analysis from historical monitoring. In the event that the method does not specify the criteria, control charts are reviewed to set laboratory internal/default QC criteria [TNI-EL-V1M4-2009-1.7.4.3.a].

For those analyses for which MS/MSD or LCS samples are not prepared, sample duplicates are analyzed to monitor performance.

The relative percent difference between duplicates or duplicate spikes is calculated as follows:

$$\textbf{RPD} = \frac{|S-D|}{(S+D)/2} \times 100$$

where;

RPD	=	Relative Percent Difference
S	=	First Sample Value (original)
D	=	Second Sample Value (duplicate)

6.2.4. External Reference Samples/Quality Control Sample (QCS)

Reference samples such as those available from NIST and EPA or other EEA approved vendors are analyzed to verify the accuracy of calibration standards. Reference standards with matrices comparable to the samples being analyzed are also included in the run whenever available.

External reference samples are analyzed immediately following the calibration standards for all inorganic and organic analyses. Appropriate reference samples for organics analyses by GC and GC/MS are less readily available and are only run when a new stock standard is prepared to verify its accuracy

6.2.5. Confirmation

Confirmation is performed to verify the compound identification when positive results are detected on a sample from a location that has not been previously tested by the laboratory. Confirmations are performed on GC organic tests such as pesticides or herbicides. GC confirmation is done following method requirements or recommendations. See method SOPs for detailed discussion of the confirmation methods. Confirmation is not required when a sample is analyzed by mass spectrometer methods. All confirmation is documented in appropriate log books/work books.

6.2.6. Retention Time Windows

Absolute retention time and relative retention time aid in the identification of components in chromatographic analyses and to evaluate the effectiveness of a column to separate constituents. The laboratory ensures that it meets the method acceptance criteria for retention time windows. If the method does not specify acceptance criteria for retention time windows, the laboratory gathers a minimum of 30 data points and calculates the acceptance criteria range using 3 times the standard deviation of the average ($\bar{x} \pm 3sd$).

6.3. DEMONSTRATION OF CAPABILITY (DOC)

6.3.1. Method Detection Limits (MDL) / Limit of Detection (LOD)

6.3.1.1. The laboratory shall utilize MDL determination by 40 CFR Part 136 as one option to provide an LOD for each analyte that is appropriate and relevant for the intended use of the data. An LOD is not required for a test method when test results are not reported outside the calibration range. LOD shall be determined by the protocol in the mandated test method or applicable regulation. If the protocol for determining LOD is not specified, the selection of the procedure must reflect instrument limitations and the intended application of the test method [TNI-EL-V1M4-2009-1.5.2.1].

6.3.1.2. The MDL shall be initially determined for the compounds of interest in each test method in a quality system matrix in which there are not target analytes nor interferences at a concentration that would impact the results of the MDL must be determined in the quality system matrix of interest [TNI-EL-V1M4-2009-1.5.2.1.d].

6.3.1.3. Method Detection Limits (MDLs) will be determined as per 40CFR, part 136, Appendix B. Essentially, this requires that an estimate of the detection limit be determined for each target analyte based on analytical experience or published references. Seven replicates of DI water must then be spiked at this estimated MDL for each method analyte carried through the entire procedure over a minimum of 3 separate analysis/extraction days. The MDL is then calculated as the standard deviation of the 7 replicates multiplied by the statistical "t-value" associated with the actual number of replicates analyzed assuming N-1 degrees of freedom (for exactly 7 replicates, the t-value is 3.143; 40 CFR, Part 136).

6.3.1.4. MDL study must be verified annually as per the EPA Manual at a minimum (or more frequently if stated in the Method such as EPA 300.0 and 353.2 where the MDL study has to be repeated every 6 months). A copy of all associated data must be submitted to the QA group for filing.

6.3.1.5. An MDL study must be repeated for each new analyst trained in a particular method, or if there is a change in the instrumentation or the test method that is used for the analysis in question. This is a necessary requirement to ensure that each new analyst has received sufficient training such that the data generated will be comparable to that of former analysts. It is necessary to repeat the MDL process with a change in instrumentation to ensure that the new instrumentation is capable of achieving equivalent sensitivity. An MDL study must also be repeated when there is any significant change in background or instrument response.

6.3.1.6. A minimum of a three-point calibration will be performed prior to the MDL study. One of the points must be at the MDL spike level. The calibration must meet all criteria outlined in the Calibration Policy.

6.3.1.7. The spiked level must be within 10 times the calculated MDL or the process must be repeated at a lower spike concentration. The spike level should be greater than the calculated level.

6.3.1.8. If there is a significant blank level, the spike level for the MDL determination must be at least three times greater than the blank concentration.

6.3.2. Minimum Reporting Limits (MRL) / Limits of Quantification (LOQ)

6.3.2.1. The Minimum Reporting Limit (MRL) is the lowest concentration normally reported to the client. It represents the reporting value linked to a specific analyte for aqueous matrix in the LIMS system. The MRL represents a conservative, nominal reporting limit designed to be representative of the minimum quantifiable concentration level for a particular analyte in a real environmental matrix as opposed to the statistically derived MDL calculation.

6.3.2.2. The MRL will generally be established by multiplying the statistically derived MDL by a factor of 2 or 3. The rationale for this approach is that the resultant value becomes approximately 10 times the standard deviation obtained during the MDL study; the EPA frequently refers to this concentration as the "Limit of Quantification (LOQ)", and defines it as the level above which accurate quantitation can be achieved. This level is also more similar to the SW-846 and SDWA concept of "Practical Quantitation Limits" (PQL). At a minimum, the MRL needs to be greater than or equal to the MDL.

6.3.2.3. Perform an MRL check and calculate the acceptance criteria for recovery of spiked analyte at MRL is 50-150 % or ± 3 standard deviations, whichever is greater if the method does not specify acceptance limits. MRL Check is run daily as per EPA Manual for the Certification of Laboratories Analyzing Drinking Water, 5th Edition.

6.3.2.4. Final MRLs should only be established after receiving input from the Group Technical Manager, Client Services Manager, Lab Director and Quality Manager. This ensures that all relevant issues regarding the selection of MRLs have been considered. These issues include specific minimum reporting limits required by a particular state or regulatory body, contractually required reporting limits for a specific client, the need to provide consistent reporting limits for our clients that have historically submitted samples associated with long-term monitoring efforts, as well as to remain competitive in the market. Thus a specific client may require that we use an MDL on our reports rather than an MRL. This deviation must be documented on client reports. A "J" flag is used to qualify results greater than MDL, but less than MRL (>MDL, <MRL). A "U" flag is used to qualify results not detected at the MDL.

6.3.3. Initial Demonstration of Capability(IDC)

6.3.3.1. An IDC is performed for each analyst and instrument. The IDC for each analyst includes a demonstration of the ability to achieve a low background, the precision and accuracy required by the method, the method detection limit (MDL) in accordance with procedure in 40 CFR 136, Appendix B and satisfactory performance on an unknown sample as on-going proficiency test result are also filed.

6.3.3.2. The IDC is repeated when there is a change in analyst, test method or instrument.

6.3.3.3. All initial demonstrations of capability and method certification shall be documented [TNI-EL-V1M3 to V1M7-2009-1.6]. A copy of the certification should be retained in the personnel records of each affected employee [TNI-EL-V1M3 to V1M7-2009-1.6.1].

6.3.3.4. Initial demonstration of method performance is completed each time there is a significant change in instrument type, personnel, or test method.

6.3.3.5. Continuing demonstration of method performance (such as laboratory control and matrix spike samples) is monitored by use of control charts.

6.3.3.6. The QC sample used for the IDC analysis is obtained from an outside source. If an external vendor is not available, the laboratory prepares the QC sample independent of the instrument calibration standard.

6.3.3.7. The QC sample concentration prepared for the IDC is approximately 1-4 times the MRL for spike concentration if not specified by the method or regulations. Four aliquots of the sample are analyzed concurrently (same day) or over a period of days. Average recovery and standard deviation for each parameter of interest are calculated in the units used for reporting to clients. The resulting average recovery and standard deviation must meet the acceptance criteria for the method.

6.3.3.8. When it is not possible to determine mean and standard deviations, such as for presence/absence and logarithmic values, the laboratory assesses performance against established and documented criteria. If there is no mandatory criteria in the method, either reference or laboratory generated limits are used.

6.3.3.9. If standards cannot be prepared, as for Microbiology, QC samples or PE samples obtained from NIST or other approved PT providers are used for the IDC. The laboratory retains all associated supporting data necessary to reproduce analytical results summarized in the IDC certification statement. The Microbiology DOC SOP provides the details of the DOC procedure.

6.3.3.10. Analysis of actual samples is not done until all parameters of interest for the IDC meet acceptance criteria. If one or more of the test parameters do not meet the acceptance criteria, the problem is corrected, followed by repeated analysis of the four aliquots for those that failed to meet criteria. If the repeat analyses fail acceptance criteria the laboratory investigates, corrects the problem and repeats the test for all parameters.

6.4. METHOD SPECIFIC QUALITY CONTROL

6.4.1. Gravimetric

6.4.1.1. All laboratory analytical balances and thermometers of ovens are calibrated annually with Class S weights and a certified thermometer. Records of this balance calibration are maintained by the balances and periodically turned in to the QA Officer for filing as records are completed. Balances are verified on each day of use.

6.4.1.2. A sufficient number of dessicators are maintained to insure that samples are not crowded to the point where they cannot cool to room temperature at the end of the specified drying period. Desiccant replacement is based on color changes.

6.4.1.3. LCS samples are analyzed at a frequency of 5 or 10% and are specified in each method SOP. At least one LCS is analyzed for each analytical run.

6.4.1.4. MS/MSD samples (or LCS pairs) are analyzed at the rate of once every batch of 20 samples of a similar matrix, or at other frequency, depending on the method requirements.

6.4.2. Titration

6.4.2.1. Use of an automated titrator set to proper delivery speed insures that every sample is titrated to the same endpoint. For manual titration, selection of the proper endpoint is achieved by comparing the color of the sample currently being titrated with the color of the previously titrated sample. The analyst must be particularly careful when performing a titration with a fading endpoint. In such instances, it is important to complete the titration as rapidly as possible.

6.4.2.2. An external reference sample is analyzed with each new set of standards or titrant to verify the accuracy of the titrant standardization and the endpoint determination. In addition, the endpoint pH is checked for each sample.

6.4.2.3. LCS samples are analyzed at a frequency of 5 or 10% and are specified in each method SOP. At least one LCS is analyzed for each analytical run.

6.4.2.4. MS/MSD samples (or LCS pairs) are analyzed at the rate of once every batch of 20 samples of a similar matrix, or at other frequency, depending on the method requirements.

6.4.3. Colorimetric Spectrophotometry

6.4.3.1. The alignment of the cell holder and light source is checked when absorbancy indicates a problem.

6.4.3.2. A minimum of three standards plus a blank, equally spaced over the concentration range, are used to calibrate the spectrophotometer in the absorbance mode, except where methods specify the use of one standard only.

6.4.3.3. The analyst records the absorbance reading for the top standard and notes on the form if a gradual increase or decrease in the absorbance of this standard is occurring. A gradual decrease in absorbance values from week to week is usually indicative of a deteriorating standard or the initial stage of lamp failure.

6.4.3.4. The rate of color development and color stability of spectrophotometric procedures varies considerably. The allowable time interval for reading the absorbance of the sample is specified in the method and must be rigidly adhered to in order to obtain accurate results.

6.4.3.5. Measuring a blank and a calibration standard after every twenty samples checks the stability of the spectrophotometer. If the baseline absorbance or the standard absorbance value has changed by more than 0.005 absorbance units or 10% from the initial calibration standard, whichever is greater, the instrument must be recalibrated and all samples analyzed since the last acceptable calibration check must be reanalyzed.

6.4.3.6. Some water samples have a natural color or turbidity which absorbs appreciably at the wavelength used in the analysis. If the sensitivity of a procedure is sufficiently high, it is usually possible to minimize this interference by diluting the sample. If the sensitivity is not adequate to permit sample dilution, the turbidity or color interference is corrected for, by reading the absorbance of the sample carried through the procedure without addition of the indicator reagent when instrumentation permits it. This absorbance reading is then subtracted as a blank from the absorbance reading of the sample.

6.4.3.7. LCS samples are analyzed at a frequency of 5 or 10% and are specified in each method SOP. At least one LCS is analyzed for each analytical run.

6.4.3.8. MS/MSD samples (or LCS pairs) are analyzed at the rate of once every batch of 20 samples of a similar matrix, or at other frequency, depending on the method requirements.

6.4.4. ICP Emission Spectroscopy & ICPMS

6.4.4.1. The sensitivity of each element is recorded in order to detect deficiencies in the instrument or operating conditions.

6.4.4.2. Reagent blanks followed by a calibration check standard are run for each metal determined with a frequency of 10%. If there is a difference of >10% from the initial standard reading, the instrument must be recalibrated and all samples that were analyzed after the last acceptable calibration check must be reanalyzed.

6.4.4.3. For ICP analysis using the simultaneous system, inter-element correction factors must be available for each wavelength used. Background correction must be used for each element.

6.4.4.4. LCS samples are analyzed at a frequency of 5 or 10% as specified in each method SOP. At least one LCS is analyzed for each analytical run.

6.4.4.5. MS/MSD samples (or LCS pairs) are analyzed at the rate of once every batch of 20 samples of a similar matrix, or at other frequency, depending on the method requirements.

6.4.5. Radiochemistry

6.4.5.1. The laboratory participates in performance studies for gross alpha and beta, Uranium and radium. Results must be within the control limits established by the vendor for each analysis.

6.4.5.2. The laboratory monitors monthly radiation measurement of laboratory instrumentation for radioactive contamination [TNI-EL-V1M6-2009-1.7.1.d]. The procedure is discussed in the CHP Manual including criteria and corrective action procedure.

6.4.5.3. Efficiency curves are run at least annually and the data recorded in the radiation notebook.

6.4.5.4. A background is run monthly for gas proportional counter, and each day of use for scintillation counter) and a known reference sample is run with each batch of radiation samples analyzed. Background check measurements shall be performed at least weekly for gas proportional counter [TNI-EL-V1M6-2009-1.7.1.c.iii]. EEA performs background check measurements each day of use for gas proportional counter. Method blank shall be performed at a frequency of at least one per preparation batch. If the acceptance criteria specified in the SOP are not met, the specified corrective action and contingencies shall be followed and the result reported with appropriate data qualifying codes [TNI-EL-V1M6- 2009-1.7.3.1.c].

6.4.5.5. LCS samples are analyzed at a frequency of 5 or 10% and are specified in each method SOP. At least one LCS is analyzed for each analytical run. The activity of LCS shall be at least10 times the Minimum Detectable Activity (MDA) or at a level comparable to that of the routine samples if the sample activities are expected to exceed 10 times the detection limit [TNI-EL-V1M6-2009-1.7.2.2.e].

6.4.5.6. Gross alpha and gross beta require MS for aqueous samples. When there is not sufficient sample aliquot size to perform a matrix spike, it shall be noted on the lab report [TNI-EL-V1M6-2009-1.7.2.3.a.iv]. The activity of the matrix spike analytes shall be greater than five times the MDA [TNI-EL-V1M6-2009-1.7.2.3.a.v].

6.4.5.7. The laboratory standards used to prepare LCS and MS shall be from a source independent of the laboratory standards used for instrument calibration [TNI-EL-V1M6-2009-1.7.2.2.f]. The MS shall be prepared by adding a known activity of target analyte.

6.4.5.8. Replicate shall be performed at a frequency of one per preparation batch where there is sufficient sample to do so. The replicate result shall be assessed against the specific acceptance criteria specified in the laboratory SOP. For low level samples (less than approximately three times the MDA) the laboratory may analyze duplicate laboratory control samples or a replicate matrix spike (matrix spike and a matrix spike duplicate) to determine reproducibility within a preparation batch [TNI-V1M6-2009-1.7.2.3.b.iv].

6.4.5.9. Consistent test conditions for RAD testing are maintained through a radiological control program that addresses analytical radiological control (See EEA's Radiation Safety Program Manual). The program shall address the procedures for segregating samples with potentially widely varying levels of radioactivity. The radiological control program shall explicitly define how low level and high level samples will be identified, segregated and processed in order to prevent sample cross-contamination. The radiological control program shall include the measures taken to monitor and evaluate background activity or contamination on an ongoing basis [TNI-EL-V1M6-2009-1.7.2.7.c].

6.4.6. <u>Gas Chromatography</u>

6.4.6.1. A laboratory water blank is analyzed for all analyses to check for artifacts from the GC system and for the presence of impurities in the water blank making it unsuitable for LCS preparation.

6.4.6.2. A field or travel blank should be analyzed for each set of field samples taken. With each set of travel blanks sent out, a stationary travel blank is kept in the laboratory for analysis to demonstrate that the water sent out was free of contamination.

6.4.6.3. A series of continuing calibration standards are run with the analysis each day for all GC analyses.

6.4.6.4. LCS and/or MS/MSD samples for assessing precision and accuracy are determined by carrying the control samples or spike and spike duplicates through the extraction procedure as well as the instrumental analysis.

6.4.6.5. LCS samples are analyzed at a frequency of 5 or 10% and are specified in each method SOP. At least one LCS is analyzed for each analytical run.

6.4.6.6. MS/MSD samples (or LCS pairs) are analyzed at the rate of once every batch of 20 samples of a similar matrix.

6.4.7. Gas Chromatography/Mass Spectrometry

6.4.7.1. GC/MS Tuning Specifications

The mass spectrometer must be shown to be properly tuned during each daily 12 hour shift. This insures that the masses and abundance's, which the data system determines, are accurate. The EPA has suggested criteria for tuning the GC/MS with two standard compounds, decafluorotriphenylphosphine (DFTPP) and 1-bromo-4-fluorobenzene (BFB). Tuning criteria are shown in Table 11-3.

The following settings are maintained:

- Emission Current: 0.5 ma
- Electron Energy: 70 ev
- Electron Multiplier: 1000-2000 volts as required for sensitivity
- Dynodes: 3000 V

For HPLC and LCMS tuning, please consult the appropriate Standard Operating Procedure for the method in question

6.4.7.2. Quantitation of Identified Compounds/Quantitation from Initial Instrument Calibration

The calibration procedure for GCMS is based on the EPA Methods Reference, for example 524.2, 525.2, 624, and 625. A minimum five point standard curve is run for all analytes. For each calibration compound a response factor (Rf) and the %RSD are calculated.

The procedure to be employed for evaluation of the acceptability of the initial calibration curve based on the EPA Methods Reference, see individual SOPs for specific examples.

All quantitation are done from initial instrument calibration and not from continuing calibration unless required by the method, regulation or program [TNI-EL-V1M4-2009-1.7.1.1.c].

6.4.7.3. Internal and Surrogate Standards (IS and SS)

The internal standard area counts are recorded for all volatile and semi-volatile samples.

If any sample is found to have an IS beyond ± 50% based on ICAL (± 30% for CCV) of the IS counts for the daily continuing calibration standard, the sample is re-analyzed unless an obvious matrix problem can be documented.

Surrogate standards are utilized in both the volatile and semi-volatile analysis.

Any volatile sample surrogate recovery that falls outside of the lab limits is immediately re-analyzed. If surrogate recoveries are still outside of the limits, a QIR is written and the report is annotated. If the second result is within the control limits, this result is reported.

For semi-volatile samples with unacceptable surrogate recoveries, the extraction run logs are examined for matrix related or other documented problems. In addition, the LCS recoveries are reviewed for the sample extraction set. If none of these indicate a matrix problem, the sample is re-extracted if still within holding times. If the analysis of the re-extract shows unacceptable surrogate recoveries, a QIR form is generated, then the sample report is annotated and the data reported.

6.4.7.4. Criteria for Tentatively Identified Compounds (TIC's)

A primary advantage of GC/MS is the ability to identify compounds for which the retention time and mass spectra are not well known to the operator. This is accomplished by performing a library search using the EPA/NIST library of mass spectra and comparing unknown to these spectra. The library search program gives five or ten of the "best fits". The best fits are determined by comparing the top eight mass fragments in the unknown to the spectra in the library. The program matches the mass numbers and the abundances at each mass number to those in the library. The program lists the possible identifications along with the numbers, which can be used by the MS operator to determine the quality of the identification. The fit is the degree to which the peaks and intensities in the unknown match those of a particular compound in the library. A perfect match would be 1000 or 1.000, depending on the software. EEA utilizes CLP criteria and method specifications for determining identification of unknowns. This includes the presence of all major ions greater than 10% relative intensity, agreement of ± 20% for major ions in the sample and reference spectra, and the review of all ions present in the sample spectrum for possible background contamination or interference.

In general a computer fit of 850 or 0.850 should be the minimum used for identification. It should be noted that even with computer library searches, there is no substitute for the judgment of a trained analyst.

6.4.7.5. Control Samples

LCS samples are analyzed at a frequency of 5%. At least one LCS is analyzed for each analytical run.

MS/MSD samples (or Duplicate) are analyzed at the rate of once every batch of 20 samples of a similar matrix, as required by TNI. Duplicates are usable only when target analytes are positives.

6.4.7.6. Blanks

Laboratory reagent water blank is normally the first sample analyzed at the beginning of each working day to demonstrate that the system is free from contamination. If the blank result indicates contamination, the system is cleaned by running additional water blanks or if necessary, finding an alternate source of contaminant free water.

6.4.8. Total Organic Carbon (TOC)

6.4.8.1. Samples are diluted to fall within the linear range of the standards.

6.4.8.2. Every tenth sample is an LCS and %recoveries must fall within acceptable control limits. MS/MSD samples (or LCS pairs) are analyzed at the rate of once every batch of 20 samples of a similar matrix as per method requirements.

6.4.9. Total Organic Halogen (TOX)

6.4.9.1. Three carbon blanks (carbon packed adsorption columns washed with nitrate-wash solution only) are analyzed at the beginning of each workday. All values must be within 20% of the average blank value obtained before standards can be run.

6.4.9.2. Each day, a set of three calibration standards is analyzed prior to analysis of samples. Calculated values for the standards must fall within 5% of the nominal value except for the 1.0 standard, which is allowed a 10% range.

6.4.9.3. Every eighth sample is, alternately, a continuing calibration standard or a carbon blank.

6.4.9.4. All samples are analyzed in duplicate. If the net values of the duplicates are not within acceptance criteria of 20%, a third and possibly a fourth replicate is analyzed.

Results are compared to the first and second replicate and the average of the two closest samples is reported.

6.4.9.5. The titration cell is revitalized by rinsing with fresh cell solution after every twenty analyses or sooner if necessary.

6.4.9.6. Samples are diluted to fall within the linear range of the standards.

6.4.9.7. Two or three serial adsorption columns from each sample adsorption are analyzed separately to determine if any organic halogen breakthrough is occurring. In the event of breakthrough, an additional diluted sample is analyzed. Every tenth sample is an LCS and %recoveries must fall within acceptable control limits.

6.4.9.8. MS/MSD samples (or LCS pairs) are analyzed at the rate of once every batch of 20 samples of a similar matrix.

6.4.9.9. The purity and adsorption capacity of each new batch of carbon purchased is assessed by duplicate analysis of an adsorption efficiency standard. This adsorption efficiency standard (standards injected into reagent water then filtered) must be within 5% of the standard value. In addition, duplicate carbon blank results must be less than 1 µg Cl-.

6.4.10. General Microbiology - Use of Commercial Dehydrated Powder for Coliform Testing

6.4.10.1. The individual collecting samples should be aware of the sampling precautions outlined in Standard Methods.

6.4.10.2. Specific sampling instructions are available from the EEA Microbiology Department. They list required precautions to follow to maintain the integrity of the samples and prevent contamination.

6.4.10.3. The maximum holding time for microbiological samples is 30 hours for drinking water and 6 hours for water/wastewater, and 8 hours for source water.

6.4.10.4. The bottles should be shipped sealed in strong plastic zip lock or bubble bags. This keeps the melting ice from contaminating the samples. Ice cubes or their equivalent must be placed around the samples but care must be taken that the samples do not freeze.

6.4.10.5. Sterility check on sample containers shall be performed on at least one container for each lot of purchased pre-sterilized sample containers. For containers prepared and sterilized in the lab, a sterility check shall be performed on one container per sterilized batch with non-selective growth media [TNI-EL-V1M5-2009-1.7.3.1.b.iii]. Microbiology sample containers are disposable high clarity polystyrene vessels with sodium thiosulfate sufficient to neutralize at minimum 5 mg/L of chlorine (IDEXX Cat No. WS216PS) for drinking water and 15 mg/L of chlorine for wastewater samples. Containers from each lot of “ready to use” are tested to ensure efficacy of $Na_2S_2O_3$ to 5 mg/L Cl_2 for drinking water and 15 mg/L Cl_2 for wastewater. Thus, samples received in the lab are not tested for additional residual Cl_2 testing [TNI-EL-V1M5-2009-1.7.5.b]. When the residual chlorine concentration is checked in the field, the result is documented in the COC.

6.4.10.6. A sterilization indicator is used during each autoclave cycle. If problems exist as indicated by a failure of the sterilization indicator, none of the items from that autoclave load is used and the group leader is notified. Demonstration of effective sterilization is provided by the use of biological indicators at least once per month of use [TNI-EL-V1M5-2009-1.7.3.7.b.ii].

6.4.10.7. Culture media are prepared from commercial dehydrated powders or ready to use media such as colilert medium. The laboratory does not prepare media or its culture media from basic ingredients. [TNI-EL-V1M5-2009-1.7.3.5.a]

6.4.10.8. Only nanopure water is used for the preparation of media. Once opened, the powdered media is tightly recapped to prevent hydration.

6.4.10.9. Prepared liquid medium is stored in the dark at refrigeration of 4°C and used within 3 months. The media is labeled with the type of medium, date prepared and the initials of the analyst who weighed out the dehydrated powder.

6.4.10.10. Prepared agar plates are stored in plastic bags, agar up, in the refrigerator. The bag is labeled to identify the type of medium, date prepared and the initials of the analyst who prepared it.

6.4.10.11. When bacteriological samples are incubated in a water bath or incubator, the temperature is recorded each morning and afternoon on the appropriate temperature sheet.

6.4.10.12. A thermometer calibrated at 44.5˚C is used for the water bath when fecal coliforms are incubated.

6.4.10.13. A positive control culture obtained from the American Type Culture Collection is inoculated for each batch of media including chromofluorogenic medium, incubated and read to indicate the acceptability of a media to a particular bacteria type. A negative control consisting of an inoculation of sterile phosphate buffer or an un-inoculated portion of media is also incubated to demonstrate the absence of contamination prior to first use of the medium.

6.4.10.14. When membrane filtration methods are used to analyze samples, a control blank of sterile dilution water is analyzed at the beginning of each set of samples. For membrane filter or plate media, duplicate counts shall be performed monthly on one positive sample for each month that the test is performed. If more than one analyst, each analyst shall count typical colonies on the same plate and count must be within 10%. If only one analyst, sample plate shall be counted twice by the analyst, with <5% difference between counts.

6.4.10.15. The laboratory analyzes a bacteriological proficiency test sample from ERA semi-annually for NELAP accreditation. The coliform test, standard plate count, is conducted on this reference sample.

6.4.10.16. A completed test is conducted on 10% of all positive coliform samples for wastewater matrix. If no positives are found, at least one positive source water or control sample is completed quarterly.

6.4.10.17. Environmental monitoring is conducted weekly using PCA plates to measure background contamination occurring from bacteria, yeast and mold carried in the air. The number of colonies on the air density plate should not exceed 15 colonies/plate/15 minutes of exposure.

6.4.11. <u>Asbestos</u>

6.4.11.1. The sampling technique follows the methods outlined by EPA in Method 100.2- Analytical Method for Determining Asbestos Fibers in Water EPA-600/R-94/134, June 1994. All samples are to be stored at 4°C until filtration and completion of analysis.

6.4.11.2. Specific sampling instructions are available from the Microbiology Department. They list precautions to follow in order to maintain the integrity of the samples and prevent contamination.

6.4.11.3. The procedure is outlined in the Method 100.2. All modifications of procedures including reasons for modifications are recorded in the SOP.

6.4.11.4. All counts for calculations and report generation are entered into LIMS to eliminate inconsistency in the final report.

6.4.11.5. The manufacturers' manuals for proper operation of all equipment used in asbestos analyses are properly filed and accessible. Records of periodic inspection, calibration and service of equipment are maintained in appropriate logbooks. Phone numbers for instrument service are posted by each instrument.

6.4.11.6. Blank using fiber-free water is processed each day that samples are filtered as stated in Method 100.2. The criterion for acceptability of bottle and process blanks is < 0.01 MFL > 10 microns in length. If this limit is exceeded, the samples filtered on the same day as the blank must be re-filtered.

6.4.11.7. All samples are filtered within 48 hours of sample collection. Samples received past 48 hours of collection are treated with O3 –UV.

6.4.11.8. The absolute (HEPA) filtration system is monitored daily and filters are changed when needed.

6.4.11.9. Asbestos glassware is prepared using sonication as stated in the method.

Table 6-1 Example of Surrogate Acceptance Limits

Method	Compound	Acceptance Limits, %
504.1/8011	1,2-Dibromopropane	60-140
524.2	4-Bromofluorobenzene	70-130
	1,2-Dichloroethane-d4	70-130
	Toluene-d8	70-130
525.2	perylene-d12	70-130
	1,3-dimethyl-2-nitrobenzene	70-130
	triphenylphosphate	70-130
531.2	BDMC	70-130
551.1	1,2-Dibromopropane	80-120
624	4-Bromofluorobenzene	70-130
	1,2-Dichloroethane-d4	70-130
	Toluene-d8	70-130
625/8270	Nitrobenzene-d5	24-118
	2-Fluorobiphenyl	24-117
	Terphenyl-d14	27-149
	2-Fluorophenol	11-126
	Phenol-d5	20-118
	2,4,6-Tribromophenol	24-141
6251 B	3,5-Dichlorobenzoic Acid	70-130
8260B	4-Bromofluorobenzene	70-130
	1,2-Dichloroethane-d4	70-130
	Toluene-d8	70-130

Note: Refer to individual SOPs for detailed Surrogate Acceptance Limits.

7.0 SAMPLE COLLECTION, PRESERVATION, IDENTIFICATION, HANDLING, AND STORAGE

Sample collection and sample handling techniques are important aspects of the overall sample analysis process and have a major impact on the validity of the results. Specific containers and preservatives are used to ensure that the analytes originally present in the sample are not lost through degradation or do not become more concentrated. In addition, contaminants that would interfere with the analysis or give erroneously high results must be mitigated.

The laboratory provides sampling instructions to all clients to guide clients on the appropriate sample collection procedures. If a client chooses to collect their own samples, experienced lab staff can brief clients by telephone or in writing through EEA's sampling collection instruction on the proper methods of sample collection. If a client chooses to hire the laboratory to do the sampling, the sampling will be done by trained sampling personnel.

7.1. SAMPLE COLLECTION AND BOTTLE PREPARATION

Production of quality analytical data requires that the collected sample is representative of the sampled area. Sampling procedures should adhere to the guidelines established by EPA and other regulatory agencies and be appropriate for the sample matrix and types of analytical parameters to be determined.

The laboratory provides sampling instructions to all clients to guide clients on the appropriate sample collection procedures. If a client chooses to collect their own samples, experienced lab staff can brief clients by telephone or in writing through our sampling collection instruction on the proper methods of sample collection. If a client chooses to hire the laboratory to do the sampling, the sampling will be done by a trained sampling personnel.

Sample bottles for all analyses except bacteriological are purchased pre-cleaned according to EPA Protocol specifications from various vendors. Certification statements for each lot of bottles are kept on file in the shipping department and each bottle is marked with its lot number. Each new lot of bottles used for volatiles analyses are checked for volatiles and trace metals contamination. All files regarding Bottle Testing are kept in the QA Files. Glass bottles are wrapped in bubble bags to prevent breakage and normally shipped to the sampling site in coolers with gel packs for chilling samples. A copy of the original kit order is included with each shipment and should be returned with properly cooled samples to the laboratory along with a properly completed chain of custody form (COC). The kit order specifies the numbers of bottles sent for each analysis and is used during the log in procedure in the laboratory.

7.2. CONTAINERS, PRESERVATIVES, HOLDING TIMES AND SAMPLE KITS

EEA supplies the appropriate sample containers, preservatives, chain-of-custody forms, coolers, and packing materials to a client upon request. The container types, bottle sizes, preservatives, container closures, and recommended holding times are shown in Table 6-1 for Drinking Water, Table 6-2 for Wastewater, and Table 6-3 for Hazardous Waste. These specifications follow CFR 136-149, Required Containers, Preservation Technique and Holding times July 1, 2011 edition and updates. Also followed is the Manual for the Certification of Laboratories Analyzing Drinking Water, Fifth Edition. Arrangements for sample kits may be made through the Client Services department. Preservatives are shipped to clients only in the specified container; bulk preservatives are not normally shipped. Only reagent grade (or better) preservatives are used. The chemicals used as preservatives are as follows:

Ascorbic Acid	Nitric acid	Sodium sulfite
Ammonium chloride	Potassium Citrate	Trizma Buffers
Copper Sulfate	Sodium hydroxide	Zinc acetate
Ethylenediamine	Sodium thiosulfate	Sodium azide
Hydrochloric acid	Sulfuric acid	Maleic Acid

Containers are delivered to the client by the following methods:
(1) Client comes to laboratory to take sample kit,
(2) Containers are sent to client by courier,
(3) Containers are shipped (via UPS/FedEx/DHL) in coolers meeting all DOT regulations.

To ensure that samples meet the temperature requirements, the laboratory checks and records the sample temperature upon receipt on the COC. The temperature check documents that the samples are kept cold (>1°C, ≤6°C), not frozen, during transport. Samples that arrive on the same day of collection and have not reached <6°C must have evidence of cooling to be acceptable.

7.3. SAMPLE STORAGE

7.3.1. Under normal circumstances storage is maintained in a refrigerator kept at 4 ± 2°C for one month from receipt [TNI-EL-V1M2-2009-5.8.9.a.i]. All samples are normally retained for at least 2 months after sample receipt or until holding times have expired, whichever is shorter. A different storage period can be arranged at the request of the client. All samples are kept in the proper storage environment for one month from receipt and then stored in the waste storage area until disposal.

7.3.2. Samples are kept in refrigerators or if storage at ambient temperature is permitted, on shelving in the designated area. Samples in the designated areas are available for the analyst to take as necessary. Documentation that these samples have been taken is available in the run log. The analyst uses their run log (Figure 8-7) as a means of tracking their samples.

7.3.3. Samples designated for volatile analysis are not kept in the same refrigerators as samples designated for non-volatile analysis.

7.3.4. Temperature in the cold storage areas is monitored twice a day at least 4 hours apart to ensure all samples meet storage temperature requirements. Storage temperatures are recorded in appropriate logbooks [TNI-EL-V1M2-2009-5.9.3.a.viii].

7.4. SAMPLE DISPOSAL

7.4.1. All laboratory wastes including excess samples, excess calibration standards, any excess test items, digestates, leachates, extracts or other sample preparation products are identified by their composition. Six waste streams are identified in the laboratory; extraction solvent, Methylene chloride wastewater, chloroform, Freon, rapid flow analyzer, corrosive acids and bases, HPLC, and flammable. Each type of waste is placed into a separate, clearly identified steel drum located in a secure area outside the laboratory. Each drum also has a characterization sheet (manifest) attached. This sheet is completed every time a waste is introduced into the drum. Drums are taken for disposal/recycling once the drum is 75 % full or every 90 days from the start date of accumulation.

7.4.2. A large majority of samples received by EEA are raw or potable waters. Residual samples, if not extracted, are disposed of by neutralizing with sodium hydroxide (NaOH) or nitric acid (HNO_3). The type and amount of waste is recorded in a logbook.

7.4.3. A continuous pH meter is attached to the effluent outfall into the city sewer to record pH of all outgoing fluids from the laboratory.

7.4.4. Hazardous waste is disposed of in 55 gallon drums. Characterization sheet is available for each type of waste or waste profile.

7.4.5. Sample disposal procedures details are available in the disposal area and available through our SOP titled, "Hazardous Waste Management and Sample Disposal Procedures". The SOP describes the requirements for the safe and effective disposal of all sample, extract and digestate waste contained in the laboratory. Means of disposal include dispensing into manifested 55 gallon drums.

7.4.6. All samples that are considered to be potentially hazardous based upon analytical results or matrix will be disposed of through a hazardous waste disposal company or a client may request that the samples be returned to them for disposal. All disposal arrangements should be made with a project manager. All samples are disposed of in accordance to RCRA and county regulations.

Table 7-1 Preservation and Holding Times for Drinking Water

(A) Inorganics – Wet Chemistry – Drinking Water
No Extract Holding Time

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Recommended Minimum Sample Size	Type of Container
Alkalinity	SM2320B	Cool, 4 ± 2°C	14 days	125 mL	Plastic
Bromate	EPA 300.1/ EPA 317.0	5mg Ethylene Diamine (EDA)/ 125 mL	28 days	125 mL	Plastic
Bromide	EPA 300.0/ EPA 300.1	None or EDA	28 days	125 mL	Plastic
Chloride	EPA300.0	None	28 days	125 mL	Plastic
Chlorate	EPA 300.0/ EPA 300.1	5 mg Ethylene Diamine/125 mL	28 days	125 mL	Plastic
Chlorite	EPA 300.0/ EPA 300.1/ EPA 317.0	5 mg Ethylene Diamine/ 125 mL Cool, 4 ± 2°C	14 days	125mL	Plastic
Color	SM2120B	Cool, 4 ± 2°C	48 hours	500 mL	Glass
Conductivity	SM2510B	Cool, 4 ± 2°C	28 days	125 mL	Plastic
Cyanide	SM4500CN-F/ EPA335.4	Cool, 4 ± 2°C, 1 mL Ascorbic acid. (if chlorinated), 1 mL NaOH, pH>12	14 days	1 L	Plastic
Fluoride	SM4500 F-C	None	28 days	125 mL	Plastic
Foaming Agents Surfactant (MBAS)	SM5540C	Cool, 4 ± 2°C	48 hours	500 mL	Plastic
Nitrate (chlorinated)	EPA300.0/ EPA 353.2	Cool, 4 ± 2°C	14 days	125 mL	Plastic
Nitrate (non-chlorinated)	EPA300.0/ EPA 353.2	Cool, 4 ± 2°C	48 hours	125 mL	Plastic
Nitrate + Nitrite	EPA 353.2 EPA 300.0	Cool, 4 ± 2°C, 0.5 mL H_2SO_4, pH<2	28 days	125 mL	Plastic
Nitrite	EPA300.0 EPA 353.2	Cool, 4 ± 2°C	48 hours	125 mL	Plastic
Odor	SM2150B	Cool, 4 ± 2°C	24 hours	500 mL	Glass
Perchlorate	EPA 314	None	28 days	125 mL	Plastic
Perchlorate	EPA 331	Sterile, Cool, 4 ± 2°C	28 days	125 mL	Plastic
pH	SM4500-HB	Cool, 4 ± 2°C	15 minutes*	125 mL	Plastic

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Recommended Minimum Sample Size	Type of Container
o-Phosphate	SM4500 P-E	Filter immediately, Cool, 4 ± 2°C	48 hours	125 mL	Polyglass Glass
Residual Disinfectant (Total/Free Residual Chlorine)	SM 4500 Cl-G	None (Analyzed on the day of collection)	15 minutes*	200 mL	Amber Glass Bottle
Silica Dissolved/ Reactive Silica	EPA 200.7 SM 4500Si-D	Cool, 4 ± 2°C	28 days	125 mL	Plastic
Solids (TDS)	SM 2540C	Cool, 4 ± 2°C	7 days	125 mL	Plastic
Sulfate	EPA 300.0	Cool, 4 ± 2°C	28 days	125 mL	Plastic
Turbidity	EPA 180.1	Cool, 4 ± 2°C	48 hours	125 mL	Plastic
Total Organic Carbon/ Dissolved Organic Carbon (DOC)	SM 5310 C/ EPA 415.3	0.5 ml H_2SO_4 to pH<2 Cool, 4 ± 2°C	28 days	125 mL	Amber Glass Bottle Teflon lined cap
UV 254/SUVA	SM 5910 B/ EPA 415.3	Cool, 4 ± 2°C	48 hours	125 mL	Amber Glass Bottle Teflon lined cap

* Must be analyzed immediately in the field for compliance.

(B) Inorganics – Metals – Drinking Water

No Extract Holding Time

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Recommended Minimum Sample Size	Type of Container
Metals (except Hg)	EPA200.7/ EPA200.8	0.5 mL HNO_3, pH<2	6 months	1 L	Plastic
Metals (Ca, Mg, K, Na)	EPA200.7	0.5 mL HNO_3, pH<2	6 months	500 mL	Plastic
Mercury	EPA245.1	2 mL HNO_3, pH<2	28 days	500 mL	Plastic
Chromium VI (Dissolved)	EPA218.6	Ammonium Sulfate/Ammonium Hydroxide Buffer, NaOH, 4 ± 2°C, pH 9.2-9.7	28 days (24 hours for DW)	125 mL	Plastic
Hardness	EPA200.7/ SM 2340B	0.5 mL HNO_3, pH <2	28 days	500 mL	Plastic

(C) Microbiology/Microscopy Tests – Drinking Water
No Extract Holding Time

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Recommended Minimum Sample Size	Type of Container
Asbestos	EPA 100.2	Cool, 4 ± 2°C	48 hours	1 L	1 L Plastic Bottle
Drinking Water Source Enumeration	SM9223 (Colilert) SM9221BE (MTF)	Cool, 4 ± 2°C, 0.2 mL of 3% $Na_2S_2O_3$	8 hours	100 mL	Sterile Plastic Bottle
Fecal Coliforms--EC Medium	SM9221E (MTF)	Cool, 4 ± 2°C, 0.2 mL 3% $Na_2S_2O_3$	30 hours	100 mL	Sterile Plastic Bottle
Heterotrophic Plate Count (Standard Plate Count)	SM9215B	Cool, 4 ± 2°C, 0.2 mL 3% $Na_2S_2O_3$	8 hours	100 mL	Sterile Plastic Bottle
Total Coliforms; By Multiple Tube Fermentation (MTF)	SM9221AB	Cool, 4 ± 2°C, 0.2 mL 3% $Na_2S_2O_3$	30 hours	100 mL	Sterile Plastic Bottle
Total Coliforms--E. Coli	SM9223	Cool, 4 ± 2°C	30 hours	100 mL	Sterile Plastic Bottle
Total Coliforms--E. Coli	SM 9223B - Colisure	Cool, 4 ± 2°C	30 hours	100 mL	Sterile Plastic Bottle
Coliphage	EPA 1602	Cool, 4 ± 2°C	48 hours	1000 mL	Sterile Plastic Bottle

(D) Organics – Drinking Water

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Extract Holding Time	Recommended Minimum Sample Size	Type of Container
DBCP/EDB	EPA504.1	3 mg Sodium Thiosulfate Cool, 4 ± 2°C	14 days	4 °C, 24 hours	40 mL	Glass with Teflon Lined Septum

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Extract Holding Time	Recommended Minimum Sample Size	Type of Container
Organohalide Pesticides and PCB	EPA 505	3 mg Sodium Thiosulfate Cool, 4 ± 2°C	14 days/ 7 days for heptachlor	4 °C, 24 hours	40 mL	Vial with PTFE-lined Screw caps
Chlorinated Herbicides (GC with Electron Capture	EPA515.4	Sodium Sulfite, dark, cool ≤ 10°C (first 48 hours, 4 ± 2°C after 48 hours)	14 days	≤0°C dark, 21 days	1 L	Amber Glass with Teflon lined Cap
Nitrosamines	EPA 521	80 – 100 mg sodium thiosulfate; Cool, 10°C (first 48 hours, 4 ± 2°C after 48 hours)	40 days	7 days	1 L	Amber glass with PTFE-lined Screw caps
Purgeable Organic Compounds/ Halogenated Aromatics, THMs, Di-Isopropyl Ether (DIPE), Tertiary Amyl methyl ether (TAME), Tert Butyl ethyl ether (ETBE) Low level TCP	EPA 524.2	25 mg Ascorbic Acid, then HCl pH < 2; Cool, 4 ± 2°C	14 days	NA	2x40 ml	Teflon Lined Septum
	EPA 524.3	25 mg Ascorbic Acid, Maleic Acid; Cool, 4 ± 2°C	14 days	NA	3x 40 mL	Teflon Lined Septum
Low Level TCP (GC/MS)	EPA 524.2/ CA DHS	Cool, 4 ± 2°C or thiosulfate, HCL pH<2	14 days	NA	2x40 ml	Teflon Lined Septum
Semi-Volatile Organics Acid/Base Neutrals, including thiobencarb (GC/MS)	EPA525.2	40-50 mg Sodium Sulfite, Dark, Cool, 4 ± 2°C, HCl, pH<2. HCL must be added after sample dechlorination	14 days	≤ 4˚C 30 days from collectio n	1 L	Amber Glass with teflon lined Cap

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Extract Holding Time	Recommended Minimum Sample Size	Type of Container
Acetanilide Pesticide Parent Compounds	EPA 525.2	40-50 mg Sodium Sulfite, Dark, Cool, 4 ± 2°C, HCl, pH<2. HCL must be added after sample dechlorination	14 days	≤ 4˚C 14 days	1 L	Amber Glass with teflon lined Cap
Pesticides and Flame Retardants	EPA 527	0.10 g/L of L-Asorbic Acid, 0.35 g/L of Trisodium EDTA, and 9.4 g/L of Potassium dihydrogen citrate; Cool, 10°C (first 48 hours, 4 ± 2°C after 48 hours)	28 days	14 days	1 L	Amber glass with PTFE-lined Screw caps
Explosives	EPA 529	0.5 g/L of Copper Sulfate pentahydrate, 5.0 g of Trizma buffer; Cool, 10°C (first 48 hours, 4 ± 2°C after 48 hours)	30 days	14 days	1 L	Amber glass with PTFE-lined Screw caps
Carbamates	EPA 531.2	0.38 g/40-mL vial Potassium dihydrogen citrate If residual chlorine is present, 6-mg of sodium thiosulfate/40-mL vial	Cool, <10°C first 48 hrs; 4 ± 2°C thereafter; dark; 28-days; pH - 3.8	< 6°C; 28-days	40 mL	Vial with PTFE-lined Screw caps
Acetanilide Pesticide Degradation Products	EPA 535	25 – 30 mg ammonium chloride; Cool, 10°C (first 48 hours, 4 ± 2°C after 48 hours)	28 days	14 days	250 mL	Amber glass with PTFE-lined Screw caps

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Extract Holding Time	Recommended Minimum Sample Size	Type of Container
Glyphosate (HPLC with Fluorescence Detector)	EPA547	6 mg Sodium Thiosulfate Cool, 4 ± 2°C	14 days (18 mo. If frozen)	NA	60 mL	Amber Glass with teflon lined septum
Endothall (GC/MS)	EPA548.1	Sodium Thiosulfate (HCl, pH 1.5-2 if high bio activity) Cool, 4 ± 2°C, Dark	7 days	14 days ≤4°C	250 mL	Amber Glass with teflon lined septum
Diquat & Paraquat (HPLC with Photoiode, Array Detector)	EPA549.2	100 mg Sodium Thiosulfate (H_2SO_4, pH<2 if bio active) Cool, 4 ± 2°C, Dark	7 days	21 days	1 L	Amber Plastic
THMs & EDB (1-2,dibromoethane) DBCP (1,2-dibromo-3-chloropropane	EPA 551.1	Sodium Sulfite, 10-50 mg NH4Cl/40 mL + 400-mg phosphate buffer/ 40 ml, Cool, 4 ± 2°C	14 days	14 days	3x60 ml	Amber Glass with Teflon lined cap
Haloacetic Acids	SM6251B	65 mg NH4Cl / 40 ml Cool, 4 ± 2°C	14 days	7 days	2 x 40 mL	Amber Glass with teflon lined cap
1,4-Dioxane	EPA 522	50 mg/L Sodium Sulfite ; 1 g/LSodium Bisulfate	14 days	30 days	2 x 250mL	Amber Glass with teflon lined cap
Dioxin	EPA 1613B	Sodium Thiosulfate Cool, 0-4°C	NA	40 days	1 L	Amber Glass with PTFE lined cap
Aldehyde	SM 6252	Cool, 4 ± 2°C	14 days	7 days	2 x 40 mL	Amber glass containers with

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Extract Holding Time	Recommended Minimum Sample Size	Type of Container
		If residual chlorine is present, 10 – 50 mg of ammonium chloride/40-mL vial				teflon-faced septa and open top screw caps

(E) Radiochemistry – Drinking Water
No Extract Holding Time

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Recommended Minimum Sample Size	Type of Container
Uranium	EPA 200.8	0.5 mL HNO_3 to pH<2	6 months	125 mL	Plastic
Gross Alpha	EPA 900.0	2.0 mL HNO_3 to pH<2	6 months	1 L	Plastic
Gross Beta	EPA 900.0	2.0 mL HNO_3 to pH<2	6 months	1 L	Plastic
Radium 228	EPA 904.0	2-mL HNO_3 per liter; pH <2	6-months, if unpreserved; after 5-days, preserve and hold in the original container for minimum of 16-hrs.before analysis	1 L	Plastic
Radon 222	SM 7500 Rn	None, no headspace	4 days	250 ml	Glass

Note: Refer to individual SOPs for preservation and holding times for all other methods not listed in Quality Manual.

Table 7-2 Preservation and Holding Times for Wastewater

(A) Inorganics – Wet Chemistry – Waste Water
No Extract Holding Time

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Recommended Minimum Sample Size	Type of Container
Alkalinity, (Bicarbonate, Carbonate, & Total Hydroxide)	SM 2320B	Cool, > 0°C , < 6°C not frozen	14 days	125 mL	Plastic
Ammonia	EPA350.1 SM4500NH3-H	Cool, > 0°C , < 6°C not frozen, 0.5 mL of H_2SO_4 to pH < 2	28 days	125 mL	Plastic
Biochemical Oxygen Demand (BOD)	SM5210B	Cool, > 0°C , < 6°C not frozen	48 hours	500 mL	Plastic
Bromide	EPA300.0	None	28 days	125 mL	Plastic
Carbon Biochemical Oxygen Demand (CBOD)	SM5210B	Cool, > 0°C , < 6°C not frozen	48 hours	500 mL	Plastic
Chemical Oxygen Demand (COD)	EPA410.4/ SM 5220D	Cool, > 0°C , < 6°C not frozen, 0.5 mL of H_2SO_4 to pH < 2	28 days	125 mL	Plastic
Chloride	EPA300.0	None	28 days	125 mL	Plastic
Chlorine, Total Residual	SM4500 Cl G	Cool, > 0°C , < 6°C not frozen	15 minutes * (immediately)	250 mL	Amber Glass
Chromium VI	SM 3500Cr-D/ EPA 218.6	Cool, > 0°C , < 6°C not frozen, Ammonia Sulfate buffer, NaOH, pH 9.3-9.7,	28 days	125 mL	Plastic
Cyanide, Total	EPA 335.4	Cool, > 0°C , < 6°C not frozen, 4 mL NAOH to pH>12, 0.6 g Ascorbic Acid (if chlorinated)	14 days	1 L	Plastic
Cyanide, Amenable to Chlorination	EPA 335.1/ SM 4500 CN-G	Cool, > 0°C , < 6°C not frozen, 4 mL of NAOH to pH>12, 0.6 g Ascorbic Acid (if chlorinated)	14 days	1 L	Plastic
Fluoride	SM4500 F-C	None	28 days	125 mL	Plastic
Hardness	EPA 200.7/ SM 2340B	1.0 mL HNO_3 to pH< 2	6 months	250 mL	Plastic
Kjeldahl Nitrogen	EPA 351.2	Cool, > 0°C , < 6°C not frozen, 0.5 mL of $H_2SO_4$to pH < 2	28 days	125 mL	Plastic

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Recommended Minimum Sample Size	Type of Container
Nitrate	EPA 353.2/ EPA 300.0	Cool, > 0°C , < 6°C not frozen	48 hours	125 mL	Plastic
Nitrite	EPA300.0/ EPA 354.1/ 353.2	Cool, > 0°C , < 6°C not frozen	48 hours	125 mL	Plastic
Orthophosphate	EPA 365.1/ SM4500 P-F	Filter Immediately, Cool, > 0°C , < 6°C not frozen	48 hours	125 mL	Plastic
Perchlorate	EPA 314.0	None	28 days	125 mL	Plastic
pH	SM4500-HB	None	15 minutes *	125 mL	Plastic
Phenols	EPA 420.4/ EPA 420.1	Cool, > 0°C , < 6°C not frozen, 2.0 mL H_2SO_4 to pH < 2	28 days	500 mL	Amber Glass
Phosphorus, Total	EPA 365.1/ SM4500 P-F	Cool, > 0°C , < 6°C not frozen,0.5 mL H_2SO_4 to pH < 2	28 days	125 mL	Plastic
Residue, Filterable (Total Dissolved Solids--TDS)	SM2540C	Cool, > 0°C , < 6°C not frozen	7 days	500 mL	Plastic
Residue, Non-filterable (Total Suspended Solids,TSS)	SM 2540D	Cool, > 0°C , < 6°C not frozen	7 days	500 mL	Plastic
Residue, Settleable (Settleable Solids)	EPA 160.5/ SM 2540F	Cool, > 0°C , < 6°C not frozen	48 hours	500 mL	Plastic
Specific Conductance	SM 2510B	Cool, > 0°C , < 6°C not frozen	28 days	125 mL	Plastic
Sulfate	EPA300.0	Cool, > 0°C , < 6°C not frozen	28 days	125 mL	Plastic
Sulfide (Total & Soluble)	SM 4500 S-2D	Cool, > 0°C , < 6°C not frozen, Zinc Acetate, plus NaOH to pH > 9	7 days	125 mL	Plastic
Total Organic Carbon (TOC)	SM 5310C	Cool, > 0°C , < 6°C not frozen,0.5 mL H_2SO_4 to pH < 2	28 days	125 mL	Amber Glass
Total Organic Halide (TOX)	SM 5320B	Sulfite & H_2SO_4	14 days	250 mL	Amber Glass
Turbidity	EPA180.1	Cool, > 0°C , < 6°C not frozen	48 hours	125 mL	Plastic

* Must be analyzed immediately in the field for compliance.

(B) Inorganics – Metals – Waste Water
No Extract Holding Time

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Recommended Minimum Sample Size	Type of Container
Metals (except Hg)	EPA200.7 EPA200.8	0.5 mL HNO_3 to pH< 2	6 months	125 mL	Plastic
Metals (Ca, Mg, K, Na)	EPA200.7	0.5 mL HNO_3 to pH< 2	6 months	125 mL	Plastic
Mercury, Hg	EPA245.1	2.0 mL HNO_3 to pH< 2	28 days	500 mL	Plastic

(C) Microbiology/Microscopy Tests – Waste Water
No Extract Holding Time

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Recommended Minimum Sample Size	Type of Container
Asbestos	EPA 100.2	Cool, > 0°C , < 6°C not frozen	48 hours	800 mL	Plastic (1 L)
Fecal Coliforms By Multiple Tube	SM9221E	Cool, > 0°C , < 6°C not frozen; 0.2 mL 3% $Na_2S_2O_3$ (if chlorinated)	6 hours	100 mL	Sterile Plastic
Fecal Streptococci/ Enterococci by MTF	SM9230B	Cool, > 0°C , < 6°C not frozen; 0.2 mL 3% $Na_2S_2O_3$ (if chlorinated)	6 hours	100 mL	Sterile Plastic
Heterotrophic Plate Count	SM9215B	Cool, > 0°C , < 6°C not frozen; 0.2 mL 3% $Na_2S_2O_3$ (if chlorinated)	6 hours	100 mL	Sterile Plastic
Total Coliforms By Multiple Tube Fermentation (MTF)	SM9221B	Cool, > 0°C , < 6°C not frozen; 0.2 mL 3% $Na_2S_2O_3$ (if chlorinated)	6 hours	100 mL	Sterile Plastic

(D) Organics – Waste Water

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Extract Holding Time	Recommended Minimum Sample Size	Type of Container
Halogenated Volatiles/ Aromatic Volatiles	EPA 624	Cool, > 0°C , < 6°C not frozen, 10 mg $Na_2S_2O_3$ for residual Cl_2,HCl** pH < 4-5	14 days	NA	40 mL	Amber Glass/ Teflon lined Septum
Semi-Volatiles, Acid and Base/ Neutral Compounds	EPA 625	Cool, > 0°C , < 6°C not frozen, 80 mg $Na_2S_2O_3$ for residual Cl_2	7 days	40 days	1 L	Amber Glass/ Teflon lined Cap

**HCl must be added after sample dechlorination

(E) Radiochemistry – Waste Water

No Extract Holding Time

Parameter/ Method Name	EPA/SM Method Number	Preservative	Sample Holding Time	Recommended Minimum Sample Size	Type of Container
Uranium	EPA200.8	0.5 ml HNO_3 to pH <2	6 months	125 ml	Plastic
Gross Alpha	EPA900.0	4.0 mL HNO_3 (18%) to pH<2	6 months	1 L	Plastic
Gross Beta	EPA900.0	4.0 mL HNO_3 (18%) to pH<2	6 months	1 L	Plastic
Radon 222	SM 7500 Rn-B	None	4 days	250 ml	Glass

Note: Refer to individual SOPs for preservation and holding times for all other methods not listed in Quality Manual.

Table 7-3 Preservation and Holding Times for Hazardous Waste (Aqueous Matrix Only)

(A) Inorganics – Wet Chemistry – Hazardous Waste (Aqueous)

No Extract Holding Time

Parameter/ Method Name	Matrix	EPA/SM Method Number	Preservative	Sample Holding Time	Sample Size	Type of Container

Note: Refer to individual SOPs for preservation and holding times for all other methods not listed in Quality Manual.

8.0 SAMPLE MANAGEMENT

8.1. SAMPLE RECEIPT AND LOG-IN/SAMPLE RECEIPT PROTOCOL

EEA receives all samples through its sample control group. Upon receipt of samples, the sample control group inspects each sample for breakage or leakage, inverted septa, inappropriate caps or bottles, air bubbles in volatile organics samples, incomplete sample labels, incomplete paperwork, or discrepancies between the sample labels and the paperwork. The sample custodian checks the sample temperature to ensure that the required temperature is maintained during transport. EPA requires for most methods that a sample temperature of 4 ± 2°C (TNI > 0, < 6˚C) shall be maintained during transport. The sample custodian records the sample temperature on the Chain of Custody. If the reading is above 6°C, the Project Manager (PM) is notified who then notifies the client regarding his sample condition. For samples that arrive at the laboratory > 6°C, the client will be notified that the affected samples are unacceptable for regulatory compliance purposes, if not received on the same day of collection with evidence of cooling, and analysis is at the discretion of the client. (Acceptance criteria as per MUR, March 12, 2007 is ≤ 6°C).

The sample custodian also screens all hazardous waste and wastewater samples from a new client with the Geiger Counter meter for presence of radiation levels above background. For additional details refer to Sample Receiving and Log-In SOP. Any sample receipt problems are recorded either on the Chain of Custody (COC) Form (Figure 8-6) for Level I or on COC and Sample Cooler Receipt Form (Figure 8-1) for Level II samples. The Client Services Manager or designated Project Manager is notified about the problems. The client is informed of these problems, the appropriate course of action is determined and a decision is made immediately whether re-sampling is required.

Sample control employees are designated to receive all shipments and deliveries to the laboratory. The procedure for receiving samples is detailed in the Sample Receipt SOP kept on file in the log-in area and central QA files. A EEA Kit Order Form (KO) is filled out for each client's samples. An example of the KO is shown in Figure 8-2. A computer assigned laboratory number is placed on each sample bottle and the bottles are stored in refrigerators segregated by receipt date.

8.1.1. Sample Labeling System

Sample bottles must be clearly labeled so that the laboratory tracking system can function optimally. All sample bottles are shipped with labels containing the particular parameters to be tested from each bottle as well as any preservative information. The client must fill in the sampling date and sample site, and the client name/identification, on the label. The sample control group insures that all returned samples contain sample site identifications.

After log-in, the sample control group attaches a label with the laboratory sample tracking number to each sample bottle. All sample bottles collected for a particular sample site normally receive the same base laboratory sample tracking number and a stamped label with this number is attached to each bottle. When analysts run a sample work schedule for their particular analysis, they receive a computer printout listing the laboratory sample numbers requiring that analysis. The analyst must then find the samples with these assigned numbers in their appropriate containers in refrigerated or non-refrigerated storage. The work schedule printout also gives the name of the client and sample ID that is compared with the information printed on the sample label to insure a proper identification.

The assigned laboratory numbers utilized for sample tracking are always a twelve-digit number. The first eight digits represent the year, month and day the sample was logged in. The remaining four digits are utilized to give each sample a unique identification number and these numbers are assigned consecutively from 1 to 9999 by the computer when the samples are logged in. These last four digits are reset back to one (1) at the beginning of each day. The laboratory also assigns a unique laboratory identification number to each sample and subsample container, and attaches a durable label to each sample container. The assignment of unique laboratory ID is done for each subsample except for samples that have short holding times. All laboratory ID codes assigned to each sample are documented in each appropriate logbooks/workbook for related laboratory activities such as sample preparation calibration and analysis.

8.1.2. Sample Receipt Acceptance Criteria:

8.1.2.1. The laboratory establishes and implements a sample acceptance/rejection policy per TNI-EL-V1M2-2009-5.8.6. The laboratory accepts a sample when the following criteria are met:

8.1.2.1.1. Proper, full, and complete documentation, which shall include sample identification, the location, date and time of collection, collector's name, preservation type, sample type and any special remarks concerning the sample;

8.1.2.1.2. Proper sample labeling to include unique identification and a labeling system for the samples with requirements concerning the durability of the labels (water resistant) and the use of indelible ink;

8.1.2.1.3. Use of appropriate sample containers;

8.1.2.1.4. Adherence to specified holding times;

8.1.2.1.5. Adequate sample volume. Sufficient sample volume must be available to perform the necessary tests.

8.1.2.1.6. Procedures to be used when sample shows signs of damage or contamination.

8.1.2.1.7. All samples, which require thermal preservation, shall be considered acceptable if the arrival temperature is ≤ 6°C, not frozen or the method specified range. For samples with a specified temperature of 4°C, samples with a temperature ranging from just above the freezing temperature of water to 6°C shall be acceptable. Samples that are hand delivered to the laboratory immediately after collection may not meet these criteria. In these cases, the samples shall be considered acceptable if there is evidence that the chilling process has begun such as arrival on ice.

8.1.2.1.8. The laboratory implements procedures for checking chemical preservation using readily available techniques, such as pH or free chlorine, prior to or during sample preparation or analysis [TNI-EL-V1M4-2009-1.7.5.b]. Residual Free Chlorine and pH testing are done for Volatile samples (524.2). Also samples for semivolatiles by 525.2 analysis and THMs by 551.1 are verified for proper preservation by checking the pH of the sample at the analyst's sample preparation area.

8.1.2.2. Results of all checks are recorded in the appropriate logbooks. If the sample does not meet the laboratory sample receipt acceptance criteria, the laboratory either:

8.1.2.2.1. Retains correspondence and/or records of conversations concerning the final disposition of rejected samples; or

8.1.2.2.2. Fully documents any decision to proceed with the analysis of samples not meeting acceptance criteria.

8.1.2.2.2.1. The condition of these samples shall, at a minimum, be noted on the chain of custody or transmittal form and laboratory receipt documents.

8.1.2.2.2.2. The analysis data shall be appropriately "qualified" on the final report.

8.1.2.3. After LIMS entries have been completed for a group, a sample acknowledgment is printed out (see figure 8-9). The original acknowledgment is emailed to the client immediately after log-in and reviewed by the client's project manager. The sample acknowledgment report allows the clients to confirm if methods and tests assigned to the samples are correct.

8.2. CHAIN OF CUSTODY

Chain of custody procedures provides legal evidence that tampering with a sample has not occurred. This is achieved by documenting an accurate written record tracing possession of the sample from collection through its final analysis and disposal. The EEA's chain of custody form provided with sample bottle shipments is presented in Figure 8-6. The laboratory maintains two levels of custody. As a standard protocol, the laboratory utilizes Level I chain of custody. Level II chain of custody is available upon request only and at an additional charge.

8.2.1. Level I

This process relies on the fact that the laboratory is a secure building. The laboratory either has custody of the sample, or not. Evidence of laboratory custody is shown through the receipt signatures on the chain of custody form. Documentation is available in the laboratory for the tracking and disposition of a sample, however this information is not intended to withstand rigorous legal scrutiny. Level I chain of custody is consistent with EPA's definition of custody. Documentation associated with this level of custody includes:

8.2.1.1. A copy of the Chain of Custody is kept in the project file.

8.2.1.2. Run logs indicating when samples were handled/analyzed.

8.2.2. Level II

Also known as Legal Chain of Custody, this process requires that the disposition of each sample be defined in terms of time and possession for the life span of the sample; from sample bottle preparation to the disposal or complete depletion of the sample during analysis. Documentation associated with this level of custody includes:

8.2.2.1. Requirements for Level I followed

8.2.2.2. Chain of custody signed by sample control personnel upon receipt of sample(s)

8.2.2.3. Airbills and/or courier receipts filed in the project file by sample control

8.2.2.4. Internal custody logbook and key to secure and separate storage refrigerators maintained by sample control personnel; all sample/extract/digestate transfers, including those to secured storage, recorded herein

8.2.2.4.1. This storage area is locked and entry is permitted only upon signing for the custody of the sample(s)/extract(s)/digestate(s).

8.2.2.5. Internal custody logbook entries include client, client sample ID, date sampled, analyses, laboratory ID, internal dates and times transferred, initials (all samples are returned at the end of each shift) see Figure 8-4.

8.2.2.6. Upon disposal the technician will complete the custody notebook (all client identifying label(s) on the container defaced or removed)

8.2.2.7. Errors deleted by drawing a single line through the item, dating and initialing and reasons clearly indicated.

8.2.2.8. Disposal of samples occur only with the concurrence of the affected legal authority, sample data user and/or submitter of the sample

8.2.2.9. Conditions of disposal and all correspondence between all parties concerning final disposition of the physical sample recorded and retained by the laboratory

8.2.2.10. Level II chain of custody sample disposal logbook (Figure 8-5) which indicates the date of disposal, nature of disposal (such as sample depleted, sample disposed in hazardous waste facility or sample returned to client, and the name of the individual who performed the task

8.2.3. Sub-contract Laboratories

When samples are sent to a sub-contract laboratory, a chain of custody is initiated by sample control or the subcontract administration group. The original chain of custody is filed in the project file with a reference to the second chain of custody. This sample is tracked internally and is identified as a subbed-out sample from an entry made into LIMs by sample control. All information from the original chain of custody is transferred to the second chain of custody in addition our internal Laboratory IDs are referenced. If samples were extracted at EEA and the extracts sent out, then the QC set for that extraction batch is sent out to the sub-contract laboratory also.

8.2.4. The Quality Manager or the Project Manager periodically inspects the chain of custody logbook to verify that analysts are signing samples back into custody the same day they are removed.

8.3. SAMPLE STORAGE AND DISPOSAL

Sample storage and disposal procedures are found in section 7.3 Sample Storage and 7.4 Sample Disposal.

8.4. SAMPLE TRACKING

When samples pass initial inspection, they are logged into the computer running the lab LIMS system. This system tracks samples from the time they arrive in the laboratory until final data are transmitted to the client. Multiple queries can be made of the database, and new routines can be written for retrieving certain information in a specified format. The following are example queries made from LIMS, printouts of these queries are available for personnel, on demand:

8.4.1. **Sample Disposition** - Shows which analyses have been performed on a given sample, which results have been validated by the manager/supervisor, and the results.

8.4.2. **Due Date/Hold time Date** - Allows analysts to schedule tests by accessing sample information according to priority date (hold time/turnaround time); query can be made per test, per group, per client, or per prompted date.

8.4.3. **QC Data** - Accessibility to QC information which can be tabulated and used to derive acceptability ranges, trend analyses, control charts etc.

8.4.4. **Formats** - Data is available for clients in various hard-copy layouts and/or electronic data format.

8.5. LABORATORY INFORMATION MANAGEMENT SYSTEM (LIMS)

8.5.1. The current Laboratory Information Management Software (LIMS) used by EEA is the STARLIMS software package developed by STARLIMS Corporation located in Hollywood, FL. The XML web based system is written in a proprietary scripted language and accesses a Microsoft SQL server.

8.5.2. The STARLIMS system provides functions to access client accounts, tests/analyses, sample tracking, test backlog generation, data entry/verification, data validation, client data in a variety of formats, monthly financial and statistical reports, and archival storage of data.

8.5.3. The security of the information contained in the LIMS is maintained through the restricted use of the database. All personnel have a unique access ID and password. The type of information entered or queried is dependent upon the level of access associated with the user.

8.5.4. LIMS has several defined user types. Access to key areas is restricted and based on the user type designated.

8.5.4.1. **Analyst/Reviewer** – Original data is entered by an analyst on an analytical batch basis (batch is no more than 20 samples). Once entered, the analyst cannot change the data nor can the analyst access the data at a higher level to review. Review must be conducted by a peer or supervisor.

8.5.4.2. **Manager/Validation** – After the secondary check, the group manager validates the data. Upon validation, the data is available to the client.

8.5.4.3. **User** – Personnel who only query the database, rather than enter data, are assigned this third level of access.

8.5.5. Final reports are uploaded to an external server (DMZ) for the client to access via a secure password and unique ID. Hardcopies are mailed upon request. Reports are electronically signed by the Project Manager before uploading to the DMZ. Invoices are mailed or electronically delivered based on client preference.

8.5.5.1. **Report Storage** – The LIMS generates an electronic file that is uploaded to an internal server. The files are stored by client/project and file type. Version numbers are noted on the file name extensions. Reports are kept electronically for 10 years. Hardcopies are no longer printed and scanned as the STARLIMS system can electronically merge all components of a final report.

8.5.5.2. **Electronic Data Deliverables (EDDs**) – Electronic data or magnetic medium data are delivered to the client using e-mail or by the client accessing the DMZ via a unique ID and password. The LIMS generates the final data report and merges this with the Chain of Custody, Acknowledgement sheet, subcontract report, case narrative, and any explanations regarding the visual sample condition into one file for the client to access.

8.5.5.3. **LIMS Maintenance** – The LIMS hardware is maintained by the IT Department of EEA and the Systems Architect/IT Manager on-site at the laboratory. The software is maintained by STARLIMS and upgrades are provided by the vendor for a yearly fee. Software validation is performed by the vendor prior to installation of the product.

A hardware/software maintenance logbook is kept with the manager of computer services. In addition to this record, all servicing performed by STARLIMS or outside vendors is documented by their staff and is available for our use.

8.5.6. Sample Status

Samples are logged into the system upon receipt in the laboratory. A laboratory number is assigned to each sample by the computer and the required tests are scheduled. Each sample then appears on the work schedule for the appropriate department. Turnaround time is automatically assigned to each sample test based on the sampling date and time and EPA holding times.

The work schedule is the primary means of checking the backlog for the analyst. The analyst can schedule the samples according to priority date, which is calculated according to the laboratory turnaround time and priority. An example of a computer generated work schedule is shown in Figure 8-8.

Operations meetings are held weekly to discuss the status of data. An Operations Report (Figure 8-10) is used by the supervisors and Project Managers during operations meetings. The Operations Report includes the group No., Client ID, Total number of Tests, Tests ready to be validated and, incomplete tests by department. The Operations Reports allow the supervisor and the project manager to monitor sample status. Also during the Operations meeting, Project managers are informed of any issues that may have arisen so that they can proactively contact the client. A list of samples with short turnaround time, 72 hours or less, is kept at sample control. Sample control contacts the analyst when short holding time samples arrive. Bottle orders are completed when clients request containers and supplies. This allows sample control to monitor the amount of samples due to arrive in the near future.

8.5.7. Data Entry and Report Generation

Data entry is accomplished through a variety of interactive sub-systems. Some situations require the entry of raw data and the system performs calculations, and reports final results and detection limits. In other cases, final data is entered either manually or via instrument interfaces. When the final scheduled test result goes into the system, the Technical Manager/Group Supervisor passes on the reports to the validation section within the system for approval. In all cases, client reports are generated and printed automatically after the verification and approval by the supervisor of each analytical group.

Results are stored in LIMS in such a manner that immediate access is available to these reports. A list of all reports completed, indexed by client number, is maintained on the system. A few keystrokes can recall every report produced for a given client. Additionally, the system provides constant information on laboratory performance. This includes turnaround times reports for every analysis done by the laboratory, and productivity reports grouped into cost isolation accounts. A weekly laboratory Turnaround time report allows the tracking of turnaround time per department to ensure that the laboratory continuously improves its turnaround time and meets client needs. See example of weekly Lab Turnaround Time Report (Figure 8-11).

The system provides several levels of security. The first level is the entry of a password to initially log on to the computer, and then the person must be designated as a qualified user. Additionally, the department to which a person is assigned governs/accesses the various functions of the system. The system also provides for read-only access to results to further protect the data from unauthorized modification or deletion.

Figure 8-1 Cooler Receipt Form

EUROFINS EATON ANALYTICAL, INC. COOLER RECEIPT FORM

PROJECT:________________________ DATE RECEIVED:________________

Use back of form to note check-in problems and describe action(s) regarding the resolution(s) of problems.

A. PRELIMANARY EXAMINATION
. Date Cooler Opened: ________________
By (print)____________________ (sign)________________________

1. Did cooler come with shipping slip (air bill, etc.)? YES NO
   If yes, attach and enter carrier and air bill number here:______________
2. Were custody seals on outside of cooler? YES NO
   If yes, how many and where:________________________________
   If yes, enter the following: seal date:______________ seal name:______________
3. Were custody seals unbroken and intact at delivery? YES NO
4. Were custody papers sealed in bag and taped to lid? YES NO
5. Were custody papers filled out properly (ink, etc.)? YES NO
6. Did you sign custody papers in the appropriate place? YES NO
7. Was project identifiable from custody papers? YES NO
8. Have designated person(s) initial and acknowledge receipt: __________ date:__________

B. LOGIN PHASE
Date samples were logged in:________________
By (print)____________________ (sign)________________________

9. Describe packing: ____
10. If required, was enough ice used? YES NO
11. Were all bottles sealed in separate plastic bags? YES NO
12. Did all bottles arrive unbroken and in good condition? YES NO
13. Were all bottle labels complete (ID, date, sign, preservative)? YES NO
14. Did all bottle labels agree with custody papers? If no, list on back. YES NO
15. Were correct containers used for the analytes? YES NO
16. Were correct preservatives used when required? YES NO
17. Was sufficient amount of sample sent for tests? YES NO
18. Bubbles absent in VOA vials? If no, list by sample ID on back. YES NO
19. Was Client Services informed of problems? YES NO

9.0 ANALYTICAL PROCEDURES

9.1. SOURCES FOR METHODS

9.1.1. **Standard Methods**

9.1.1.1. The laboratory shall evaluate the Precision and Bias of a standard method for each analyte of concern for each quality system matrix according to the single-concentration four-replicate recovery study procedures in TNI-EL-V1M3 to V1M6-2009-1.6.2.2 (or alternate procedure documented in the quality manual when the analyte cannot be spiked into the sample matrix and QC samples are not commercially available) [TNI-EL-V1M4 and V1M6-2009-1.5.3.a].

9.1.1.2. The analytical methods performed by EEA are based primarily on methods specified by various federal, state, and local regulations. If more stringent standards or requirements are included in the mandated test method or by regulation than the TNI standard, the laboratory ensures that all SOPs meet such requirements. If it is unclear which requirements are more stringent, the laboratory follows the requirements from the method or regulation. All analysts must follow all the Quality Control protocols and all essential QC measures specified by the laboratory's SOPs. The majority of methods come from the U.S. Environmental Protection Agency. Other methods are from Standard Methods for the Examination of Water and Wastewater, 19th, 20th, and online Editions. Additional methods may be used when appropriate.

Methods from the EPA are listed in section 9.6, the references section.

9.1.2. **Non Standard Methods**

9.1.2.1. Methods not covered by standard methods are properly validated before use. Non-standard methods when used by the laboratory are subjected to agreement with the Client incorporating the Client's specification requirements, including the purpose of the environmental test. The method is validated appropriately before use [TNI-EL-V1M3 to V1M4-2009-1.4].

9.1.2.2. For laboratory-developed test methods or non-standard test methods as defined in TNI-EL-V1M2- 2009-5.4.3 and ISO/IEC 17025:2005(E)-5.4.3 and TNI-EL-V1M3 to V1M7-2009-1.4 that were not in use by the laboratory before July 2003, the laboratory must have a documented procedure to evaluate precision and bias. The laboratory must also compare results of the precision and bias measurements with criteria established by the client, by criteria given in the reference method or criteria established by the laboratory.

9.1.2.3. Laboratory developed methods may be used when the client does not specify the method to be used or where methods are employed that are not required by regulations, as in the Performance Based Measurement System Approach, the methods shall be fully documented and validated (TNI-EL-V1M2-2009-5.4.2) (ISO/IEC 17025:2005(E)-5.4.2) and TNI-EL-V1M3 to V1M7-2009-1.4), and be available to the Client and other recipients of the relevant reports. The laboratory shall select appropriate methods that have been published either in international, regional or national standards, or by reputable technical organizations, or in relevant scientific texts or journals, or as specified by the manufacturer of the equipment. Laboratory-developed methods or methods adopted by the laboratory are used only if appropriate to the intended use and are validated. The laboratory informs the Client as to the method chosen. [TNI-EL-V1M2-2009-5.4.2][ISO/IEC 17025:2005(E)-5.4.2]

9.1.2.4. The laboratory informs the Client when the method proposed by the Client is considered to be inappropriate or out of date. [TNI-EL-V1M2-2009-5.4.2][ISO/IEC 17025:2005(E)-5.4.2]

9.1.3. The introduction of environmental test and calibration methods developed for the laboratory for its own use is a planned activity and is assigned to qualified personnel equipped with adequate resources.

9.2. INITIAL TEST METHOD EVALUATION PROCEDURES

For all test methods (other than microbiology or methods where LOD/LOQ determinations are not relevant) the following LOD and LOQ requirements apply.

9.2.1. Limit of Detection (LOD)

9.2.1.1. The laboratory shall determine the LOD by performing the MDL studies determination to conform to CFR136 for the method for each target analyte of concern in the quality system matrices. All sample-processing steps of the analytical method shall be included in the determination of the LOD.

9.2.1.2. The validity of the LOD shall be confirmed by quantitative identification of the analyte(s) in a QC sample in each quality system matrix containing the analyte at no more than 1-3X the LOD for single analyte tests and 1-4X the LOD for multiple analyte tests. This verification must be performed on every instrument that is to be used for analysis of sample and reporting data. LOD verification Acceptance Criteria is detection (>0).

9.2.1.3. An LOD study is not required for any component for which spiking solutions or quality control samples are not available such as temperature, or, when test results are not to be reported to the LOD (versus the method reporting limit or working range of instrument calibration). Where an LOD study is not performed, the laboratory may not report a value below the Limit of Quantitation. Since the EPA Manual for Drinking Water 5th Edition requires MDL studies, the laboratory conducts MDL determinations for all drinking water methods where applicable. EEA does not report down to the LOD but reports down to the LOQ.

9.2.2. Limit of Quantitation (LOQ)

9.2.2.1. The laboratory shall determine the LOQ for each analyte of concern according to a defined, documented procedure. LOQ/MRL is 2-3x LOD/MDL. At a minimum, LOQ/MRL > LOD.

9.2.2.2. The LOQ study is not required for any component or property for which spiking solutions of quality control samples are not commercially available or otherwise inappropriate (e.g., pH).

9.2.2.3. As per TNI Std, the validity of the LOQ shall be confirmed by successful analysis of a QC sample containing the analytes of concern in each quality system matrix 1-2 times the claimed LOQ. A successful analysis is one where the recovery of each analyte is within the established test method acceptance criteria or client data quality objectives for accuracy. This single analysis is not required if the bias and precision of the measurement system is evaluated at the LOQ. EEA verifies the validity of the MRL/LOQ daily at the MRL level as per EPA Manual for DW 5^{th} edition.

9.2.2.4. Precision and Bias

Precision and bias measurements must evaluate the method across the analytical calibration range of the method. The laboratory must also evaluate precision and bias in the relevant quality system matrices and must process the samples through the entire measurement system for each analyte of interest [TNI-EL-V1M4 and V1M6-2009-1.5.3].

Examples of a systematic approach to evaluate precision and bias could be the following for non-standard methods:

9.2.2.4.1. Analyze QC samples in triplicate containing the analytes of concern at or near the limit of quantitation, at the upper-range of the calibration (upper 20%) and at a mid-range concentration. Process these samples on different days as three sets of samples through the entire measurement system for each analyte of interest. Each day one QC sample at each concentration is analyzed. A separate method blank shall be subjected to the analytical method along with the QC samples on each of the three days. (Note that the three samples of the MRL concentration can demonstrate sensitivity as well). For each analyte, calculate the mean recovery for each day, for each level over days, and for all nine samples. Calculate the relative standard deviation for each of the separate means obtained. Compare the standard deviations for the different days and the standard deviations for the different concentrations. If the different standard deviations are all statistically insignificant (e.g., F-test), then compare the overall mean and standard deviation with the established criteria from above.

9.2.2.4.2. A validation protocol such as the Tier I, Tier II, and Tier III requirements in US EPA Office of Water's Alternate Test Procedure (ATP) approval process.

9.2.2.5. Selectivity

The laboratory evaluates selectivity by following the checks established within the method, which may include mass spectral tuning, second column confirmation, ICP inter-element interference checks, chromatography retention time windows, sample blanks, spectrochemical absorption or fluorescence profiles, co-precipitation evaluations, and electrode response factors [TNI-EL-V1M4-2009-1.5.4].

9.2.3. Detection Limits

9.2.3.1. The method used in the quantitation of detection limits is as described in 40 CFR 136 Appendix B, which in summary is the analysis of at least seven replicates from which a statistically derived Method Detection Limit (MDL) is calculated. The replicates are determined over at least a 3 day period. This statistically derived limit is based on 3.143 times the standard deviation of 7 low concentration replicates (3-5 times the calculated detection limit). It is the laboratory's policy to be conservative when reporting a method detection limit on a non-detected sample.

9.2.3.2. Consequently, the laboratory has implemented the concept of minimum reporting levels (MRLs). The limit used on a laboratory report must be at or above the lowest standard associated with that analytical run. This ensures that all data reported as "detected" will have some degree of analytical precision associated with it. Data reported below these levels must be appropriately qualified. Copies of current MRLs for the laboratory are available upon request. An MRL can be no lower than the calculated MDL.

9.2.3.3. For newer methods, a Lowest Concentration Minimum Reporting Level (LCMRL) may be required before client samples may be run on the method, annually, and for any new analysts. The LCMRL is essentially a more strict verification of the MRL. See the appropriate method for the exact requirements of an LCMRL and its verification. Section 9.2.4 of EPA Method 524.3 details the requirements for the 524.3 LCMRL, for example.

9.3. ESTIMATION OF UNCERTAINTY

Estimation of uncertainty consists of the sum (combining the components) of the uncertainties of the numerous steps of the analytical process, including, but not limited to, sample plan variability, spatial and temporal sample variation, sample heterogeneity, calibration/calibration check variability, extraction variability, and weighing variability.

The laboratory estimates uncertainty using 2 times standard deviation calculated from 20 routine quality control samples with a guidance of <20% RSD. Refer to the Nonmethod 29 SOP for detailed Measurement Uncertainty procedures.

9.4. METHOD VALIDATIONS [TNI-EL-V1M3 to V1M7-2009-1.5]

9.4.1. The laboratory shall validate non-standard methods, laboratory-designed/developed methods, standard methods used outside their published scope, and amplifications and modifications of standard methods to confirm that the methods are fit for the intended use. The validation shall be as extensive as is necessary to meet the needs of the given application or field of application. The initial test method evaluation requirements given in V1M3 to V1M7 1.6 of TNI Standard 2009 and 2011 discussed in Section 4.4, MDL and IDC requirements for new analysts are done in validating new methods and non-standard methods [TNI-EL-V1M3 to V1M7-2009-1.5]. This is also applicable when an analyte not currently found on the laboratory's list of accredited analytes is added to an existing accredited test method. Initial evaluation must be performed for that analyte [TNI-EL-V1M4 and V1M6-2009-1.6.2.2.g]. The laboratory records the results obtained for the IDC, MDL, LOD and LOQ studies. The method is fit for the intended use when the results meet all the MDL and IDC criteria for the method.

9.4.2. The range and accuracy of the values obtainable from validated methods (e.g. the uncertainty of the results, detection limit, selectivity of the method, linearity, limit of repeatability and/or reproducibility, robustness against external influences and/or cross-sensitivity against interference from the matrix of the sample/test object), are assessed for the intended use, and relevant to the Client's needs [TNI-EL-V1M7-2009-1.4].

9.5. METHOD VALIDATION/MICROBIOLOGY

To demonstrate the suitability of a test method for its intended purpose, the laboratory meets the acceptance criteria by the EPA or State program requirements. Also, the laboratory must meet the following criteria as per TNI-EL-V1M5-2009-1.5.2 and 1.5.3:

9.5.1. Accepted (official) test methods or commercialized test kits for official methods from recognized national or international standards organizations do not require a specific validation. However to demonstrate proficiency with the test method prior to first use, the laboratory performs comparison to a method already approved for use in the laboratory, or by analyzing a minimum of ten spiked samples whose matrix is representative of those normally submitted to the laboratory, or by analyzing and passing one proficiency test series provided by an approved proficiency sample provider. The laboratory shall maintain this documentation as long as the method is in use and for at least 5 years past the date of last use [TNI-EL-V1M5-2009-1.5], or 10 years to meet Massachusetts, Hawaii, and New York requirements.

9.5.2. The laboratory participates in the proficiency test programs identified by NELAP [TNI-EL-V1M1-2009-4.1.1 and 4.2.1.a] or [TNI-EL-V1M2-2009-5.9.1.b][ISO/IEC

17025:2005(E)-5.9.1.b]. The results of these analyses are used to evaluate the ability of the laboratory to produce acceptable data.

9.6. METHODS USED/SCOPE OF TESTING

9.6.1. The analytical methods used by EEA can be grouped into three major categories: drinking water methods, wastewater methods, and methods for hazardous wastes and solid samples. The following tables provide method descriptions and method numbers for the methods used in these three major groups:

Table 9-1 Method Description for Drinking Water

Table 9-2 Method Description for Wastewater

Table 9-3 Method Description for Hazardous Waste

9.7. METHOD MODIFICATIONS

All method modifications are documented fully in individual SOPs. Methods are modified if and only if the original method goals for precision and accuracy have been met or better. Modifications are usually implemented due to available resources, or to expedite the process without sacrificing quality. Methods are validated prior to analyzing client samples. Validation is based on the method as described in the internal SOP. The validation includes an MDL study, an analyst precision and accuracy study, and subsequent review by the Technical Manager, Lab Director and Quality Manager.

(A) Inorganics – Wet Chemistry – Drinking Water

Parameter/Method Name	Method Number	Method Description	Reference
Alkalinity	SM2320B	Titrimetric	4/4e
Ammonia	EPA350.1	Colorimetric	1
Bromate	EPA 300.0 / 300.1 / 317.0	Ion Chromatography	6/16/23
Bromide	EPA300.0/300.1	Ion Chromatography	6/16
Chloride	EPA300.0	Ion Chromatography	6
Chlorate	EPA 300.0/300.1	Ion Chromatography	6/16
Chlorite	EPA300.0/300.1 / 317.0	Ion Chromatography	6/16/23
Chromium VI (Dissolved)	EPA 218.6/ SM 3500 Cr-B	Ion Chromatography	2/4
Color	SM2120B	Visual	4
Conductivity	SM2510B	Wheatstone Bridge	4
Cyanide	SM4500CN-F,G	Selective Electrode Method	4
Cyanide	EPA335.4	Manual Distillation, Spectrophotometric	6
Fluoride	SM4500 F-C	Potentiometric - Ion Selection Electrode	4
Fluoride	EPA 300.0	Ion Chromatography	6
Foaming Agents/ Surfactant (MBAS)	SM5540C	Colorimetric	4
Nitrate/Nitrite	EPA300.0	Ion Chromatography	6
Nitrite/Nitrate + Nitrite	EPA 353.2	Automated Cadmium Reduction, RFA	1
Odor	SM2150B	Odor	4
Perchlorate	EPA 314.0 EPA 331	Ion Chromatography LCMS	6
pH	EPA 150.1/SM4500-HB	Electrometric	1/4
o-Phosphate	EPA 300.0	Ion Chromatography	6
o-Phosphate	SM4500 P-E EPA 365.1	Color, Ascorbic Acid	4/6
Residual Chlorine (Total/Free Chlorine)	SM4500 Cl-G	DPD Colorimetric/HaCH	4
Silica	EPA200.7	ICP	2
Dissolved Silica/Reactive Silica	SM 4500 SiO2C SM 4500 SiD	Molybdosilicate	4
Solids (TDS)	SM2540C	Gravimetric	4
Sulfate	EPA300.0	Ion Chromatography	6
Temperature	SM2550B	Thermometric	4
Total Organic Carbon(TOC)/ Dissolved Organic Carbon (DOC)	SM5310C	UV Persulfate	4

Parameter/Method Name	Method Number	Method Description	Reference
Turbidity	EPA180.1 SM 2130B	Nephelometric	6/4/4e
UV 254	SM5910B	Determination of UV absorbing organic constituents by UV absorption method at 254 nm	4
TOX (Total Organic Halogen) or Dissolved Organic Halogen (DOX)	SM 5320B	Adsorption-Pyrolysis-Titrimetric Method	4

(B) Inorganics – Metals – Drinking Water

Parameter/Method Name	Method Number	Method Description	Reference
Metals (except Hg)	EPA 200.7	ICP (Inductively Coupled Plasma)	2
Metals (except Hg)	EPA 200.8	ICPMS (Inductively Coupled Plasma Mass	2
Mercury	EPA 245.1	Manual Cold Vapor	2

(C) Microbiology/Microscopy Tests – Drinking Water

Parameter/Method Name	Method Number	Method Description	Reference
Drinking Water Source Enumeration (MTF)	SM9221B,C	Multiple Tube Fermentation (MTF)	4/4d
Drinking Water Source Enumeration/Colilert 24 hr & 8 hr	SM9223B	MMO-MUG Test/Colilert	4/4d
Fecal Coliforms/EC Medium	SM9221E	Multiple Tube fermentation (MTF) / EC Medium	4/4d
Heterotrophic Plate Count	SM9215B	Pour Plate Count	4/4d
Total Coliform & E. Coli	SM9223B	Colisure	4/4d
Total Coliforms	SM9221A, B	Multiple Tube Fermentation (MTF)	4/4d
Total Coliforms + --E. Coli / Present or Absent	SM9223B	MMO-MUG Test/Colilert	4/4d
Coliphage	EPA 1602	Coliphage	20
Asbestos	EPA 100.2	TEM (Transmission Electron Microscopy)	8

(D) Organics – Drinking Water

Parameter/Method Name	Method Number	Method Description	Reference
DBCP/EDB	EPA504.1	Microextraction, GC/ECD	3d
Organohalide Pesticides and Commercial Polychlorinated Biphenyl (PCB) Products in water by Microextraction and Gas Chromatography	EPA505	Microextraction, GC/ECD	3d

Parameter/Method Name	Method Number	Method Description	Reference
Chlorinated Herbicides	EPA515.4	GC, Electron Capture Detector (ECD)	18
Purgeable Organic Compounds/ Halogenated & Aromatic Volatiles/Trihalomethanes/Di-isopropyl Ether(DIPE),Tertiary Amyl Methyl Ether (TAME), Tert-Butyl ethyl ether (ETBE), TBA, CS2, MIBK 1,2,3-Trichloropropane (TCP)	EPA524.2 CA DHS 524.2-SIM	Purge and Trap capillary Column, GCMS	3d
Semi-Volatile Organics -- Acid/Base Neutrals including ThioBencarb	EPA525.2	Liquid Solid Extraction (LSE), capillary column, GCMS	3d
N-Methylcarbamoyloximes and N-Methylcarbamates	EPA531.2	HPLC with Fluorescence Detector	19
Glyphosate	EPA547	HPLC/Post Column Reactor - Fluorescence Detector	3a
Endothall	EPA548.1	GCMS, Liquid Solid Extraction (LSE)	3b
Diquat & Paraquat	EPA549.2	HPLC, Liquid Solid Extraction (LSE) UV Detector	24
Trihalomethanes & EDB/DBCP	EPA 551.1	GC, Electron Capture Detector (ECD), liquid liquid extraction	3d
Haloacetic Acids	SM6251B	GC, Electron Capture Detector (ECD)	4
1,4-Dioxane	EPA 522	GCMS, Solid Phase Extraction (SPE)	21
Nitrosamines	EPA 521	GCMS-MS, Solid Phase Extraction (SPE)	22
Dioxin	EPA 1613B	GC/EI/MS/MS, Solid Phase Extraction (SPE)	25
Volatile Organic Compounds	EPA 524.3	GC/MS	26
Selected Pesticides and Flame Retardants	EPA 527.0	GC/MS, Solid Phase Extraction (SPE)	27
Haloacetic Acids and Dalapon	EPA 552.3	GC, Electron Capture Detector	28
Chloroacetanilide and Other Acetamide Herbicide Degradates	EPA 535	LC/MS/MS, Solid Phase Extraction (SPE)	29
Explosives	EPA 529	GC/MS, Solid Phase Extraction (SPE)	30

(E) Radiochemistry – Drinking Water

Parameter/Method Name	Method Number	Method Description	Reference
Uranium	EPA 200.8	ICP MS	2

Parameter/Method Name	Method Number	Method Description	Reference
Gross Alpha	EPA900.0	Proportional Counting	11
Gross Beta	EPA900.0	Proportional Counting	11
Radium 226/228	Georgia Inst. Of Tech, rev 1.2	Gamma-ray Spectrometry Using HPGE Detector	31

Table 9-2 Method Description for Wastewater

(A) Inorganics – We Chemistry – Wastewater

Parameter/ Method Name	Method Number	Method Description	Reference
Alkalinity, Total (Bicarbonate, Carbonate, & Hydroxide)	SM2320B	Titrimetric, Potentiometric	4/4e
Ammonia	EPA350.1/SM 4500 NH3H and D (18th)	Colorimetric	1/4a
Biochemical Oxygen Demand (BOD)	SM5210B	BOD/Probe	4
Boron	EPA200.7	ICP	2
Bromide	EPA300.0	Ion Chromatography	6
Carbonaceous Biochemical Oxygen Demand (CBOD)	SM5210B	BOD/Probe with Nitrification Inhibitor	4
Chemical Oxygen Demand (COD)	EPA410.4, SM5220D	Colorimetric	1/4
Chloride	EPA300.0	Ion Chromatography	6
Chlorine, Total Residual	SM4500 Cl G	Spectrophotometric, DPD, HACH	4
Chromium VI	EPA 218.6/ SM3500D Cr-B	0.45 micron Filtration Followed by Colorimetric or Ion Chromatography	2/4
Color	SM2120B	Visual	4
Cyanide, Total	EPA 335.4	Manual Distillation followed by Auto Spectrophotometric	1
Cyanide	SM4500-CN F	Ion Selective Electrode	4
Cyanide, Amenable to Chlorination	SM 4500CN G	Automated Colorimetric after treatment	4
Dissolved Oxygen (DO)	SM 4500-OG	Membrane Electrode	4
Fluoride	SM4500 F-C	Ion Selective Electrode	4
Fluoride	EPA 300.0	Ion Chromatography	6
Foaming Agents/ Surfactant (MBAS)	SM5540C	Colorimetric	4

Parameter/ Method Name	Method Number	Method Description	Reference
Hardness	EPA 200.7/SM 2340B	Calculation Ca plus Mg as CO3-	2/4
Kjeldahl Nitrogen	EPA351.2	Colorimetric, Semi-auto block digester	1
Nitrate	EPA353.2 EPA300.0	Cadmium Reduction Ion Chromatography	1/6
Nitrite	EPA300.0 EPA 353.2	Ion Chromatography Cadmium Reduction	6/1
Total Residue	SM 2540B	Gravimetric	4
Orthophosphate	SM4500 P-E/PF, EPA 365.1, EPA300.0/HACH 8048	Manual Single Reagent Ion Chromatography	4/6
Perchlorate	EPA 300.0/314.0	Ion Chromatography	6
Phenols	EPA 420.1/420.4	Manual Distillation Followed by Colorimetric	1
pH	SM4500-HB	Electrometric	4
Phosphorus, Total	SM4500 PE EPA 365.1	Persulfate Digestion followed by Manual Colorimetric	4/6

10.0 PURCHASING SERVICES AND SUPPLIES/ MEASUREMENT TRACEABILITY

10.1. PURCHASING SERVICES AND SUPPLIES

10.1.1. Documented procedures for the purchase, receipt and storage of reagents and standards (consumable materials) used for the technical operations of the laboratory must be followed by all personnel as per TNI-EL-V1M2-2009-5.6.4.2. Refer to the Nonmethod 27 SOP for detailed procedures for Purchasing Services and Supplies.

10.1.2. Purchased supplies and services that affect the quality of environmental tests are of the required quality by using approved suppliers and products.

10.2. REAGENTS AND REFERENCE STANDARDS

10.2.1. All chemicals used by EEA are ACS Reagent Grade, or better. Wherever possible, standards are from sources that are traceable to the National Institute for Standards and Technology (NIST). The laboratory ensures the use of reagents of same or better purity than that specified in the method. Thus, the analyst checks the label of the container to verify that the purity of the reagents meets the requirements of the particular method. The purchased supplies and reagents that affect the quality of the tests are not used until they are inspected or otherwise verified as complying with requirements defined in the test method.

10.2.2. Procedures shall be in place to ensure prepared reagents meet the requirements of the test method [TNI-EL-V1M2-2009-5.6.4.2.e]. If the method does not specify reagent quality, at a minimum the laboratory uses analytical “Reagent Grade” or better quality for all reagents.

10.2.3. Calibration Standards

10.2.3.1. Stock standards are obtained from the EPA Repository, or suppliers traceable to NIST, for the organic compounds. The metal stock solutions are obtained from NIST traceable sources. Initial calibration verification standards are obtained from a second “Manufacturer or lot” if lot can be demonstrated from the manufacturer as prepared independently from other lots [TNI-EL-V1M4-2009-1.7.1.1.d]. Stock solutions for surrogate parameters and other inorganic compounds are made up by the analysts from the appropriate reagent grade chemical specified in the procedure.

10.2.3.2. Stock standards are utilized to make working standards of lower concentration, which are then used to make calibration standards for the analytical run. The holding periods of stock standards, working standards, and calibration standards for the different analyses are provided in Table 10-2.

10.2.3.3. Stock standards, working standards, and calibration standards are all prepared in accordance with the method procedure. A logbook is maintained for standards preparation providing the initials of the analyst preparing the standard, the date of preparation, the concentration made up, and the lot numbers and suppliers. Since only one set of working standards is prepared at a time, the date of an analytical run can be keyed to the date of the working standards preparation to provide traceability to the particular lots of reagents from which the calibration standards were derived.

10.2.3.4. Calibration standards are run at the beginning of each day's analysis and a single standard is run every 10 samples throughout the analysis and at the end of the run to check for instrument drift. This "check" standard can also be used as an additional measure of analytical precision in addition to the LCS. Beginning and ending check standards must be at varying concentration within the established calibration range. If an internal standard is used, one CCV check must be analyzed per batch and an ending CCV may not need to be run unless required by method.

10.2.3.5. At the beginning of each day of analysis, all instruments must be calibrated. The calibration standards used must encompass a range of low, mid and high level concentrations to determine the calibration curve. The low level standard must be at or below the MRL value, the high level standard must be at the high end of the calibration range range and the mid level standard must be approximately midway between the low and high concentrations. Calibration procedures vary for the different instrumental methods and are summarized on Table 11-1. Section 11.1 for some representative methods.

10.2.4. **Policy on Verification of Standards**

All information relating to standards preparation and verification must be documented in the Standards Preparation notebook for that analysis. All documentation required must be examined by the analyst and signed off by the section supervisor. All documentation for each group must be stored in a central location (i.e. the standards preparation room). For microbiology, performance checks including the organisms used, their culture collection reference, date of issue of specification, or statements assuring that the relevant batch meets the product specifications is verified [TNI-EL-V1M5-2009-1.7.3.6].

10.2.4.1. **Mixtures**

New standard mix preparations must be compared to the previous mix. The concentrations calculated for the new standard should be within 10% of the "true" value (or as per the specific SOP). If the new standard does not agree within 10%, a third standard must be prepared by a different analyst and compared to the previous two. The third standard should agree with either the "old" standard or the "new" standard. If the third standard agrees with the "old" standard the third standard is used as the "new" standard. If the third standard agrees with the "new" standard the "old" standard is discarded and both the "new" and third standards can be used. In both cases the "new" standard must be verified by comparing to a "known" reference standard before discarding the old standard. Note that for some methods it may not be possible for the new standard to agree within 10% (see the specific SOP).

A new calibration curve must be prepared analyzing both the new standard and a known reference sample. The calculated value must fall within the acceptance limits for the reference sample.

10.2.4.2. **Neat Compounds**

The identity and purity of any new bottle of neat material must be verified either by the method it will be used to monitor or, preferably, by a different method.

For Organics, a solution of the new neat material must be compared to the old standard as a check on identity and purity. Acceptance criteria are detailed in the previous Mixtures section. For inorganics the new stock standard must be compared to the old stock standard as a check on concentration.

10.3. DOCUMENTATION RECORDS OF REAGENTS AND STANDARDS

10.3.1. A logbook is maintained for all standards. Each log contains the date of fresh stock preparation, the manufacturer’s lot number and supplier, the preparer's initials, the weight of material and the final volume used to prepare the stock.

10.3.2. The laboratory shall retain records for all standards, reagents, reference materials and media including the manufacturer/vendor, the manufacturer’s Certificate of Analysis or purity (if supplied), the date of receipt, recommended storage conditions, and an expiration date after which the material shall not be used unless it is verified by the laboratory [TNI-EL-V1M2-2009-5.6.4.2].

10.3.3. Original containers (such as provided by the manufacturer or vendor) shall be verified and labeled with an expiration date [TNI-EL-V1M2-2009-5.6.4.2.b].

10.3.4. Records shall be maintained on standard and reference material preparation. These records shall indicate traceability to purchased stocks or neat compounds, reference to the method of preparation, date of preparation, expiration date and preparer’s initials.

10.3.5. Where traceability to NIST is not applicable, the laboratory shall provide satisfactory evidence of correlation of results, example participation in proficiency testing or independent analysis of reference standards and reference materials [TNI-EL-V1M2-2009-5.6.4.1].

10.3.6. All containers of prepared standards and reference materials must bear a unique identifier and expiration date, and be linked to documentation requirements in 10.3 above [TNI-EL-V1M2-2009-5.6.4.2.d].

10.3.7. All containers of prepared reagents must bear a preparation date. An expiration date shall be defined on the container or documented elsewhere as indicated in the laboratory's quality manual or SOP [TNI-EL-V1M2-2009-5.6.4.2.d and 5.9.3.a.vi].

10.4. REAGENT STORAGE AND DISPOSAL

10.4.1. Standards are stored in designated refrigerators or freezers. Samples/extracts/digestates are not stored in these refrigerators due to the potential for cross-contamination.

10.4.2. All reagents, solvents and reactive chemicals are stored in their original containers in appropriate cabinets or storage closets specifically designed for this use. See Table 10-1, for storage instruction. Date received and date opened must be recorded on each reagent container.

Table 10-1 Reagent and Standard Storage

Chemical	Method of Storage
Nitric Acid	Stored in original containers in cabinet designed for acid storage.
Hydrochloric Acid	Stored in original containers in cabinet designed for acid storage.
Sulfuric Acid	Stored in original containers in cabinet designed for acid storage.
Flammable Solvents	Stored in original containers in flammable storage cabinets.
Oxidizers	Stored separately from flammable in cabinet designed for oxidizers.
Ethyl Ether	Stored in original containers in flammable storage cabinets. New lots are tested for peroxides. Each bottle is tested before and after peroxide removal with an activated alumna column
Stock Standard Solutions	Stored in freezer at 0°C in unbroken ampoules
Working Standard Solutions	Stored in refrigerator at 4°C labeled with prep information and expiration date.
Reagent Chemicals	Stored in cabinets in air conditioned laboratory areas
Hazardous Chemicals	Any chemical which is a health toxin and a known carcinogen, is stored in a secured area with restricted access

11.0 CALIBRATION PROCEDURES AND FREQUENCY

The production of analytical data of known, defensible and documented quality requires adherence to standardized procedures, which cover all aspects of laboratory operation. The following sections provide details of the standardized procedures relating to instrumentation calibration.

11.1. INITIAL INSTRUMENT CALIBRATION

Prior to use, every instrument must be calibrated according to a specified procedure found in the method-specific SOP. Table 12-1 lists all major laboratory equipment. Table 11-1 lists the minimum calibration frequency of use and the acceptance criteria for the various calibration techniques, on a method by method basis. Table 11-2 also summarizes the calibration methods and number of calibration standards that are used on an instrument basis. Table 11-3 lists the ion abundance tune criteria, which must be met during calibration, for mass spectroscopy methods such as 524.2 and 525.2. Calibration frequency and criteria included in the tables are only for representative test methods. Calibration procedures for other methods can be found in relevant SOPs.

Each instrument, and support equipment including reference standards of measurements such as Class S weights or equivalent weights, and traceable thermometers are marked and identified to indicate its calibration status such as "Calibration due date."

11.1.1. **Applicability**

11.1.1.1. The creation of this or any other policy is designed to be a guideline to ensure that all data are treated alike, and thus ensuring that data generated on any particular day of analysis are representative of the norm. The policies are not intended to be absolute criteria for the acceptance or rejection of any analytical data.

11.1.1.2. There is no substitute for the inherent familiarity that each analyst has with his or her specific analysis, and consequently their assessment of the data must be considered in cases where the acceptance criteria outlined in policy or SOPs cannot be achieved. Data generated in situations where one or more of the requirements outlined cannot be met will be reviewed on a case-by-case basis by the QA staff and the appropriate Technical Manager for acceptance. A detailed Quality Investigation Report (QIR) should have been completed and included in the data package to justify any deviation from policy or SOP protocols. Example of a QIR is shown in Figure 15-2.

11.1.2. **Linearity**

11.1.2.1. All calibrations should be linear unless otherwise defined in the specific SOP and allowed by the reference method. Many organic methods may allow or require the use of a quadratic fit for some compounds. Linearity here is defined as a calibration curve that meets the back-calculation criteria presented below, unless the SOP contains different criteria. Specific protocols outlined in a given SOP will always take precedence over generic policies outlined in this QA Manual.

11.1.2.1.1. Linear Regression

y = mx + b

Where:

y = Response A_x for External Standard or A_x/A_{is} for Internal Standard
x = Concentration C_x for external standard, or C_x/C_{is} for internal standard
m = Slope
b = Intercept

11.1.2.1.2. Linear Regression Statistical Equations

Slope (m) → $m = \frac{[(Swx_i y_i \times Sw) - (Swx_i \times Swy_i)]}{[(Sw \times Swx_i^2) - (Swx_i \times Swx_i)]}$

Intercept (b) → $b = y_{ave} - (m \times (x_{ave}))$

Correlation Coefficient (r) →

$$r = \frac{[(SW \times Swx_i y_i) - (Swx_i - Swy_i)]}{\sqrt{[Sw \times Swx_i^2) - (Swx \times Swx_i)] \times [(Sw \times Swy_i^2) - (Swy_i \times Swy_i)]}}$$

Coefficient of Determination (r^2) → $r^2 = r \times r$

Where:

n = number of x, y pairs
x_i = individual values for the independent variable
y_i = individual values for the dependent variable
w = weighting factor, for equal or no weighting w = 1
x_{ave} = average of the x values
y_{ave} = average of the y values
S = the sum of all the individual values

11.1.2.1.3. Quadratic Regression Equation

$y = ax^2 + bx + c$

Where:
y = Response A_x for external standard, or A_x/A_{is} for internal standard
x = Concentration Cx for external standard, or Cx/Cis for internal standard

11.1.2.1.4. Equation for Concentration

External Standard Equation → $C_x = \frac{(A_x - b)}{m}$

Internal Standard Equation → $C_x = \left(\frac{A_x/A_{is} - b}{m}\right) C_{is}$

11.1.2.2. If the method does not specify the acceptance criteria for the linear fit, the laboratory will establish a policy for acceptance criteria of 0.995 for correlation coefficient. The calibration curve is verified using any one of the following:

11.1.2.2.1. Coefficient of Determination (r^2)

$$r^2 = \frac{S(y_i - y_{ave})^2 - [{(n-1)}/{(n-p)} \times (S(y_i - Y_i)^2]}{S(y_i - y_{ave})^2}$$

Where:

y_i = individual values for each dependent variable
x_i = individual values for each dependent variable
y_{ave} = average of the y values
n = number of pairs of data
p = number of parameters in the polynomial equation (i.e., 3 for third order, 2 for second order

$$Y_i = \frac{\left\{\left[2a \times \left({C_x}/{C_{is}}\right)^2\right] - b^2 + b + (4ac)\right\}}{4a}$$

S = the sum of all the individual values

11.1.2.2.2. An initial calibration verification standard (ICV's) is immediately run after the curve. The standard is preferably obtained from a 2nd source or different lot if the lot can be demonstrated from the manufacturer as prepared independently from other lots [TNI-EL-V1M4-2009-1.7.1.1.d]. Concentrations that lie in the middle of the curve should have an acceptable recovery of ± 10% of the true value.

11.1.2.2.3. The linear curve will be acceptable if the curve meets the back-calculation criteria, i.e. back calculating the initial calibration standards against the developed model, with an acceptance criteria of ± 10 % recovery of the true value.

11.1.3. **Selection of Quantitation Technique (Organics)**

11.1.3.1. For organic analysis, a decision must be made during the validation process (and detailed in the SOP) as to whether an internal or external quantitation technique will be routinely employed.

11.1.3.2. The internal standard method of quantitation cannot be employed unless all of the following conditions are met:

11.1.3.2.1. The internal standard must be added post-extraction. For Method 525.2, it is added pre-extraction.

11.1.3.2.2. The internal standard must be added quantitatively.

11.1.3.2.3. Any analyte that is a target analyte using the method of interest may not be selected for use as the internal standard.

11.1.3.2.4. The concentration of the internal standard(s) must not exceed the calibration range of the method target analytes. In cases where the target analytes are associated with more than one calibration range (i.e. analytes "1-4" are calibrated from 1 to 10 µg/L, while analyte "5" is calibrated from 10 to 100 µg/L, and analytes "6-10" are calibrated from 2.5 to 25 µg/L), the concentration of the internal standard should be prepared at a level between the highest calibration standard of the highest and lowest absolute calibration range. (e.g. approximately 50 µg/L in the example given).

11.1.3.3. The use of internal standard quantitation is of greatest benefit in those methods subject to a great deal of injection variability, and thus a great deal of variability in the absolute mass injected onto the column(s) employed. The drawback to this technique for GC methods is that any compound that exhibits a similar retention time as the compound used for the internal standard will be identified as the internal standard, leading to erroneous quantitation. For this reason, the internal standard technique is most useful for GC/MS where deuterated analytes not naturally occurring can be detected and quantified.

11.1.4. **Selection of Calibration Method**

11.1.4.1. During the method validation process, a least square regression is initially tried as a calibration method. The responses from each of the calibration standards must then be input into the linear regression equation to determine whether or not the corresponding concentrations meet the acceptance criteria outlined below. If the acceptance criteria cannot be met using a linear regression, then a second order polynomial fit can be used to fit the data, with $r^2 \geq 0.99$ as the acceptance criteria. In the event that neither a simple linear regression nor a second order polynomial fit result in an equation which meets the calibration acceptance criteria, then the calibration range must be broken down into two or more smaller ranges. Each of the subsequent ranges must individually meet all of the requirements for a single calibration range. If a linear regression works, a single average response factor may be used if the calibration is linear through the origin and it is consistent with the referenced method.

11.1.4.2. As part of the validation process, the specific calibration range and calibration algorithm must be determined and documented in the SOP. Once determined in this manner, the same protocols must be followed each time the method is employed. This will ensure that data reduction is not performed differently on separate data sets or by different analysts.

11.1.5. **Minimum Number of Calibration Levels**

The calibration for linear fits must include a minimum of three initial calibration standards plus a blank unless specified otherwise in the SOP. Polynomial fits must include at least 5 standards. The minimum requirement for a NELAP Lab as per TNI-EL-V1M4-2009-1.7.1.1.j is: a minimum of three (3) standards (one of which is lowest quantitation limits, not including a blank or zero standard), if the reference method does not specify the minimum number of initial calibration standards.

11.1.6. **Selection of Calibration Levels**

11.1.6.1. To avoid weighting a calibration curve to create a better fit than is warranted, three standards must be included per order of magnitude of concentration of the calibration curve. For example 0.1, 0.5, 1.0, 5.0, 10.0 has 3 standards per order of magnitude (0.1, 0.5 and 1.0, and 1.0, 5.0 and 10.0).

11.1.6.2. The lowest calibration standard shall be the lowest concentration for which quantitative data are to be reported. Any data reported below the lower limit of quantitation is considered to have an increased quantitative uncertainty and is reported using either "J" flags or explained in the case narrative [TNI-EL-V1M4-2009-1.7.1.1.f].

11.1.6.3. The highest calibration standard shall be the highest concentration for which quantitative data are to be reported. Any data reported above the highest standard is considered to have an increased quantitative uncertainty and is reported using "E" flags or explained in the case narrative [TNI-EL-V1M4-2009-1.7.1.1.g].

11.1.6.4. Measured concentrations outside the working range are reported as having less certainty and are reported using "E" flags or explained in the case narrative. The lowest calibration standard must be above the limit of detection, usually at MRL level except for ICP that allows zero point and single point calibration. [TNI-EL-V1M4-2009-1.7.1.1.h].

11.1.6.5. A good approach to select calibration levels when the calibration range is expected to span at least one order of magnitude is to set the levels at 1 MRL, 5 MRL, and 10

MRL for a simple 3 point calibration. If more points are desired, then they would follow the same scheme, i.e. 50 MRL, 100 MRL.

11.1.7. **Calibration Analytical Sequence**

11.1.7.1. The calibration must progress from the analysis of the lowest to highest standard unless the instrumentation does not permit it or the method requires calibration from high to low. A blank must be analyzed after the highest calibration standard.

11.1.7.2. If the analysis requires an initial high standard to set the gain a blank must be run before starting with the low calibration standard unless the instrumentation does not permit it.

11.1.8. **Calibration Acceptance Criteria**

For linear fits, in general, the calculated value for standards (using the calibration curve or response factor) must be within 10% of the nominal value for mid-level standards. However, the value determined by the calibration curve for the lowest standard (conc. is at the MRL) must be within ± 50% of the true value or ± 25% of the true value if the lowest standard is >5X & <10X MRL. Accurate quantitation at the MRL level may require use of a second order fit or separation of the curve into multiple linear segments. Mid level standards (conc. > 10X MRL) should be within ± 10% of the true value. Relevant SOPs should be reviewed for the method and laboratory calibration verification specific criteria, which may be different from those stated here.

11.2. CONTINUING INSTRUMENT CALIBRATION

11.2.1. Continuing calibration (CC) is run as required by the method. Refer to specific SOPs to determine the frequency and acceptance criteria of continuing calibration verifications.

11.2.2. The continuing calibration standard must be near the mid-point of the calibration curve unless the method requires rotation of concentration levels.

11.2.3. The calculated value for the continuing calibration standard must be within control limits stated in the specific SOP.

11.2.4. Calibration shall be verified for each batch for each compound, element, or other discrete chemical species, except for multi-component analytes such as Aroclors, Chlordane, or Toxaphene where a representative chemical related substance or mixture can be used.

11.2.5. Instrument calibration verification must be performed:

11.2.5.1. At the beginning and end of each analytical batch (except, if an internal standard is used; only one verification needs to be performed at the beginning of the analytical batch). As per Standard Methods sections 1020 and 3020, run CCVs every 10 samples.

11.2.5.2. Whenever it is expected that the analytical system may be out of calibration or might not meet the verification acceptance criteria.

11.2.5.3. If the time period for calibration of the most previous calibration has expired, or

11.2.5.4. For analytical systems that contain a calibration verification requirement.

11.2.6. If the method does not specify criteria for the acceptance of a continuing instrument calibration, verification must be established, e.g., relative percent difference.

11.2.7. If the continuing instrument calibration verification results obtained are outside established acceptance criteria, corrective actions must be performed.

11.3. UNACCEPTABLE CONTINUING INSTRUMENT CALIBRATION VERIFICATIONS

11.3.1. If routine corrective action procedures fail to produce a second consecutive (immediate) calibration verification within acceptance criteria, then either the laboratory has to demonstrate acceptable performance after corrective action with two consecutive calibration verifications, or a new initial instrument calibration must be performed.

11.3.2. If the laboratory has not verified calibration, sample analyses may not occur until the analytical system is calibrated or calibration verified. If samples are analyzed using a system on which the calibration has not yet been verified the results shall be flagged.

11.3.3. If these criteria are not met, a second continuing calibration standard must be run (either freshly prepared or a second injection, as appropriate). No individual analyte can fail the CC criteria two consecutive times. If the criteria are still not met, a new initial calibration must be run and the new calibration curve verified. The laboratory qualifies the data with "V" flag if the sample data is associated with failed calibration verification.

11.3.4. As per TNI-EL-V1M4- 2009-1.7.2.e, data associated with an unacceptable calibration verification may be fully useable under the following special conditions:

11.3.4.1. If there was a high bias and there is a failed continuing calibration verification, the lab reports only data associated with samples that are non-detects.

11.3.4.2. If there was a low bias and there is a failed continuing calibration verification, the lab reports only data associated with samples that have a result greater than the maximum regulatory limit/decision level.

Table 11-1 Minimum Calibration Frequency and Acceptance Criteria

Analysis	Method	Calibration Technique	Acceptance Frequency	Criteria
Organohalide Pesticides and PCB products	505	Endrin Breakdown Initial Calibration	Daily beginning and end of analysis	< 20% degradation % RSD ≤20
		Cal Verification Std	beginning and end of analysis	80 – 120 %
		LRB	before start of analysis; each time set of samples extracted or reagents changed	< RL
		LFB	Every 20 samples (all samples extracted within a 24-hr period) points	%R = 70 – 130% Require control charts after 30 data
		MRL checks	Daily	50 – 150% Requires control charts after 30 data points
		LFM IDC, 7 LFBs QCS	Every 10 samples Initial set up, new analyst Quarterly	%R = 65-135 % ≤ 20 % RSD, 70 – 130 % R
Volatile Organics Including DIPE, TAME, ETBE Low level 1,2,3-TCP	524.2	BFB Sensitivity	Every 12 hours of operation	Ion abundance criteria (Table 11-3)
		Initial Calibration (7-pt)	Prior to analysis, or when CC fails	RSD ≤20 % / r≥0.995
		Continuing Calibration	After BFB tune and every 12 hours of operation and at the end of analytical batch (highly recommended by Method)	RF within 30% of the initial calibration
		Surrogate	added to CCV, every sample & all initial calibration stds. (Not required for TCP).	70-130 % Rec
		MS/MSD (upon client request)	Every 20 samples. (Not required for TCP).	70-130 % Rec.
		LCS/LFB	Every 20 samples Every 12 hrs or every 10 samples (TCP)	70-130 % Rec. 80-120 % Rec. (TCP)
		LFB Dup (TCP: can be used in place of Lab Duplicate)	Quarterly	RPD <20%
		Blank	Every 20 samples. Every 10 samples for TCP.	<MRL
		QCS (TCP)	Quarterly (TCP)	%R = 80-120% (TCP)
		MRL checks	Daily	± 50% of the true value
		Lab Duplicate (TCP)	1 per 10 samples (TCP)	% RPD < 20% (TCP)

Analysis	Method	Calibration Technique	Acceptance Frequency	Criteria
Volatile Organics	524.3	BFB Sensitivity	Prior to initial calibration	Refer to Table 1 in 524.3 SOP
		Initial Calibration (7-pt)	At the start of the analytical up or when CCV fails	Cal. Points ≤MRL: ±50% Other cal. Points: ±30%
		ICV/QCS	After initial calibration and quarterly	70-130% Rec
		Continuing Calibration Check	After every 10 field samples	%D for each analyte below MRL: ≤50% Above MRL: ≤30%
		LRB	1 per analytical batch	< ½ MRL
		Matrix Spike/LFSM	1 per analytical batch	70-130% Rec
		LFBD	At least quarterly	70-130% Rec RPD: <20%
		Surrogate	Every sample, QCs, DCCs	70-130% Rec
		Internal Standards	Every sample and calibration standards	±30% of most recent CCC ±50% of average response in ICAL
Semi- Volatiles Organics	525.2	DFTPP Sensitivity	At the beginning of each 12 hours that samples are analyzed	See Table 11-3
		Endrin/DDT Degradation Check	Daily, each 12 hours, before sample run	<20% breakdown
		Initial Calibration	Prior to analysis, when CC fails	< 30% RSD
		Continuing Calibration	Beginning of each 12 hours and every 12 hours that are analyzed and at the end of analytical batch (highly recommended) by Method)	70-130% Rec
		MS	5 % or 1 per sample set Extracted whichever is more frequent	70-130 % Rec
		LCS/ LFB	5 % or 1 per sample set Extracted whichever is more frequent	70-130 % Rec
		Method Blank	1 per sample extraction set	< RL
		Surrogates	added to each sample before extraction	% R =70-130%
		MRL Checks	Analyzed with each extraction batch	50 – 150% Requires control charts after 30 data points
		IS	added to each sample before extraction	area count must not decrease by >50 % from initial calibration and 30% from CCC.

Analysis	Method	Calibration Technique	Acceptance Frequency	Criteria
Trihalomethane /Chloral Hydrate/ Haloacetonitrile /EDB/DBCP	551.1	Initial calibration (Extracted)	Beginning of analysis	< 10 % RSD
		Lab Performance Check	Beginning of analysis	Table 7 of the method
		Endrin Breakdown	Beginning of analysis	< 20 %
		Calibration verification (CCV=LFB)	Before start of analysis, every 10th sample, and after the final sample analysis	% R = 80-120 % for 90 % analytes & 75-125 % for all analytes
		LRB (Lab Reagent Blank)	1 per extraction Batch	< ½ MRL
		LFB (Lab Fortified Blank)	Every 10 samples. (Not Required).	% R = 80-120 % for 90 % analytes & 75-125 % for all analytes
		LFM	every10 samples	80-120 %
		LFM/Duplicate	see sample duplicate	see sample duplicate
		Sample Duplicate	10 % or at least 1 per set, whichever is greater	RPD < 20 for 90 % of analytes, RPD <25% for all analytes
		Surrogate	All samples	80-120 %
		QCS	Quarterly	same as CCV
		IDC, 7 LFBs	Initial set up new analyst	R = 80-120 %, < 15 % RSD
		Stock solutions Verification; Outside Source.	every new lot	< 20% RPD
Volatile Organics	624	BFB Sensitivity	Prior to ICAL and calibration verification, every 12 hours of operation	Ion abundance criteria (Table 11-3)
		Initial Calibration	Prior to analysis, or when CC fails	RF <35 % RSD
		Continuing Calibration (QC Check Std)	After BRB tune, every 12 hours of operation	All analytes' %R must meet % R as specified in Table 5 of Method 624 (See SOP)
		Surrogate	added to CCV, every sample & all initial calibration stds.	%R as specified in SOP
		MS/MSD	Every 20 samples	All analytes' %R must meet % R as specified in Table 5 of Method 624
		MRL check	Daily, prior to sample analysis	50 – 150% Requires control charts after 30 data points
		LCS/LFB	Every 20 samples	All analytes' %R must meet % R as specified in Table 5 of Method 624

Analysis	Method	Calibration Technique	Acceptance Frequency	Criteria
Base Neutrals and Acids	625	DFTPP Sensitivity	Every 12 hours of operation	Ion abundance criteria (Table 11-3)
		Initial Calibration	Prior to analysis, when CC fails	All analytes <35% RSD
		Continuing Calibration (same as MRL Check)	Every 12 hours of operation	All analytes w/in ±20% Of the predicted response
		MS/LFM	Every 20 samples	All analytes' %R must meet % R as specified in Table 6 of the method
		LCS/LFB	Every 20 samples	All analytes' %R must meet % R as specified in Table 6 of the method
HAA	6251B	Calibration curve	each batch	<20%RSD or r ≥ 0.995
		Method Blank	1 per batch of 20 samples or less	< ½ MRL
		LCS/ LFB	1 per sample set Extracted or 20 samples	LCS: 80-120% Mid and High LFB : ±15%
		MRL check	1 per sample set extracted or 20 samples	50-150%
		MS/LFM	1 per 10 sample set extracted	Control Chart Limits updated annually
ICP Metals	200.7/ 6010	ICV	Following calibration	95-105% Rec, <3% RSD
		Method blank	Every 20 samples	< ½ MRL
		MS/MSD	Every 10 samples	70-130%, 75-125% (6010B)
		MRL Check	Beginning and end of the run	50 – 150%
		LCS/LFB	2 per batch of 20 samples	85-115%
ICPMS Metals	200.8/ 6020	Tuning Solution	At the start of QC program or after major maintenance or every 2 weeks	Good Performance: 0.75 amu peak width at 5% peak height Mass calibration: <0.1 amu from unit Mass Instrument stability: 5x run; <5% RSD
		Quality Control Sample(QCS)	Quarterly	90 –110%
		Initial Calibration Verification	Immediately following calibration	95–105% Rec
		Calibration blank	Each batch	< ½ MRL
		Linearity Check 5x CCV/upper limit of Calibration Range	Prior to sample sequence	90-110% Rec
		Replicate Integration	3 replicates	≤ 10% RSD at higher concentrations

Analysis	Method	Calibration Technique	Acceptance Frequency	Criteria
ICPMS Metals (con't.)	200.8/ 6020	Continuing Calibration Verification (CCV)	Every 10 samples	90-110 % Rec
		Minimum Report Limit (MRL), Check/CRDL	Beginning of analysis and end of the sample run	50-150%
		Laboratory Fortified Matrix (LFM)	Every 10 samples	70-130% Rec
		Laboratory Fortified Matrix (LFM) Duplicate	2 in every 20 samples	70-130% Rec 20% RPD
		LCS/LFB	One per batch of 20	85-115% Rec
		Internal Standards (IS)	Spike each sample, standard and blank	60-125% of the response in the calibration blank
		Method Blank	1- per batch of 20-samples	<1/2 MRL or <1/2 CRDL
		Instrument Blank	Prior to Calibration	< ½ MRL
Cr VI (Dissolved)	218.6/ 3500CrB	Initial Calibration	Daily at the beginning of each run	$r \geq 0.999$
		IPC(CCV)	1-per 10 samples	95-105 % Rec
		LRB (Lab Reagent Blank)	1-per 10 samples	< ½ MRL
		LFB/QCS	1-per batch of 20 samples	90-110% Rec (external source)
		LFM	1-per 10 samples	90-110% Rec
		LFMD	1-per batch of 20 samples	90-110% Rec (RPD <20%)
		MRL Check	Daily	50 – 150%
		QCS	Quarterly (see LFB)	90-110%
		LDR	Start of program	minimum 7 stds

Automated Wet Chemistry:

Analysis	Method	Calibration Technique	Acceptance Frequency	Criteria
Cyanide Fluoride Nitrate Nitrite Phenolics	335.4, 9012B SM4500F C 353.2, 300.0 300.1 420.1, 420.4	Linear Calibration curve (7-11 pt)	Each batch	$r \geq 0.995$ (correlation coefficient)

TOC	SM 5310C	Calibration curve (6-pt)	Every 6 months or until instrument drifts	r ≥ 0.995 correlation
		Blanks	At the beginning of batch and every 10 samples	< 0.250ppm

Analysis	Method	Calibration Technique	Acceptance Frequency	Criteria
TOC (con't.)	SM 5310C	MS/MSD	MS: Every 10 samples MSD: Every 20 samples/batch	80-120%
		LCS/LFB/CCV	At the beginning of batch and every 10 samples	90-110 %
		MRL Check	Daily	50-150%
		LCS1/MRL Check	Every batch	50-150%
		Lab Duplicate	All samples	≤10 % RPD (TOC ≥ 2.0 mg/L) ≤15% RPD (TOC < 2.0 mg/L)
UV 254	SM 5910B	Calibration curve (3-pt) Verification	Prior to analysis of samples	90-110 %
		Blank/UV absorbance @ 254	At the beginning of batch and after every 10 samples	< 0.004 units
		LCS/LFB UV absorbance @ 254 nm	At the beginning of analysis	Agrees within manufacturer's listed range
		MRL Check	Daily	50-150%
		Lab Duplicate	All samples analyzed in duplicate	≤10% RPD ≤15% RPD for low standards

NOTE: 1) Any deviations from the listed criteria are specified in the SOP.
2) Concentrations for all continuing calibrations are in the middle of the linear range.
3) For all other methods not listed in the Quality Manual, see calibration frequency and acceptance criteria in individual SOPs.

Table 11-2 Calibration Procedures

Instruments	Minimum # of Calibration Standards	Calibration Method
TOX	3 points standard (for precision only)	Titration
Anions, Nutrients (Ion Chromatography)		
Nitrate, NO3 Nitrite, NO2 Chloride, Cl2 Sulfate, SO4	11-points 11-points 7- points 10-points	Quadratic Quadratic Quadratic Quadratic
Phenol, Cyanide	5 point	Linear Regression
Fluoride	3 point minimum	Linear Regression (log)
pH	3 point	Slope
Radiation	5-6 points	Efficiency Curve
TOC (TOC Analyzer)	6 Point	Linear Regression
UV 254 (Spectronic 601) Spectrophotometer	3 Point	Efficiency Curve
524.2 (GCMS)	5-7 Points	Linear Regression
HAA (GC)	5 Point	Linear Regression

Note: For all other methods not listed in the Quality Manual, see calibration procedures in individual SOPs.

Table 11-3 Ion Abundance Criteria (Tune Criteria)

(A) BROMOFLUOROBENZENE (BFB) (524.2 and 624)

Mass	Ion Abundance Criteria
50	15 - 40% of mass 95
75	30 - 60% of mass 95 (624) ; 30-80 % mass 95 (524.2)
95	Base peak, 100% relative abundance
96	5 - 9% of mass 95
173	Less than 2% of mass 174
174	Greater than 50% of mass 95
175	5 - 9 % of mass 174
176	Greater than 95%, and less than 101% of mass 174
177	5 - 9% of mass 176

(B) DECAFLUOROTRIPHOSPHINE (DFTPP) (525.2)

Mass	Ion Abundance Criteria
51	10-80% of the Base Peak
68	Less than 2% of mass 69
70	Less than 2% of mass 69
127	10-80% of the base peak
197	Less than 2% of mass 198
198	Base Peak or >50% of 442
199	5 - 9% of mass 198
275	10 - 60% of the base peak
365	Greater than 1% of the base peak
441	Present, but less than mass 443
442	Base Peak or Greater than 50% of mass 198
443	15-24% of mass 442

Table 11-4 Initial Calibration Acceptance Criteria

Anions/Nutrients	Initial calibration value for standards must be within 10% of the nominal value. $r \geq 0.995$
GC	Initial Calibration RF <20% RSD or second order fit, continuing calibration. RF ≤ 20% Difference. Must meet specific method calibration criteria.
GCMS, EPA 524.2	Initial Calibration ≤ 20 % RSD, $r \geq 0.995$
HAAs	Initial Calibration correlation coefficient $r \geq 0.995$, < 20 % RSD
HPLC	Correlation coefficient must be ≥0.995 or 20% RSD
Metals	Initial calibration value for standards must be within 5% of the nominal value.
pH	Values for 4, 7, 10 buffers must be ± 0.1 pH unit of the nominal value
Radiation	Each calibration standard counts must be >10,000.
TOC	Initial calibration value for standards must be within 10% of the nominal value. $r \geq 0.995$
TOX	Initial calibration value for standards must be within 10% of the nominal value. $r \geq 0.995$
UV 254	Initial Calibration value for the standards must be within 10 % of the normal value.

12.0 EQUIPMENT

12.1. ANALYTICAL EQUIPMENT

12.1.1. All equipment is properly maintained, inspected, and cleaned.

12.1.2. Table 12-1 contains a list of the major analytical equipment used during sample preparation and analysis. For Microbiology, pressure cookers are not used for sterilization of growth media [TNI-EL-V1M5-2009-1.7.3.7.b.ii].

12.2. SUPPORT EQUIPMENT

12.2.1. Balances

Analysts are responsible for daily calibration verification checks of the analytical balances in the laboratory with Class S weights and annual calibrations of the drying ovens thermometer with an NIST traceable certified thermometer. Documentation of the balance and oven checks is maintained in the appropriate logbook. Reference certified thermometers are calibrated every five years. A yearly thermometer calibration check is done for all other thermometers and all thermometers are labeled showing any necessary correction to achieve true readings. Balances are calibrated annually and Class S-weights are calibrated every 5 years by an outside vendor. Copies of these balance and thermometer records are filed with the QA records for the laboratory. All Class S weights and traceable thermometer standards are used for calibration only and for no other purpose to ensure that the performance as reference standards are always valid.

Balance calibration is verified on the day of use prior to weighing samples, standards or reagents. If balance does not meet the acceptable criteria of ± 0.1 % or other vendor recommended limits, the analyst reports to QA that balance needs service. The instrument is labeled “out of service” until repaired. The Analyst records the problem and identifies corrective action, date of service, and if corrective action resolved the problem.

12.2.2. Temperature Monitoring

Refrigerators, incubators, temperature are monitored 2 times daily in at least 4 hour intervals. If the temperature measured is not meeting the acceptance criteria of 4± 2°C, analyst reports to the QA department. QA then monitors the temperature after 2 hours and more often if needed. If non-compliance is still observed, QA calls for service. The instrument is labeled “out of service” until repaired. QA records the problem identified, corrective action, date of service, if called, and if corrective action resolved the problem.

12.2.3. Pipets

Eppendorf pipette function verification is done on the day the standards are prepared for pipets used for the preparation of both the primary and secondary standards. Monthly frequency is done for pipets used either for the preparation of either the primary or secondary standards and for Class A pipets used for the preparation of the other set of standards. When used over a range of settings, the pipet is calibrated at the highest and lowest settings. If not meeting the acceptable range of ± 2 % of the set value, the analyst investigates and identifies the problem. The pipet is cleaned if needed and inspected for signs of wear or damages or for residual liquids that may have been sucked in the pipet. After the appropriate Corrective Action, the pipet is again calibrated. Corrective Action taken and problem identified is recorded. If corrective action did not resolve the problem, the analyst documents in the logbook that the pipet is off-line. The pipet is also labeled "out of service" until repaired.

12.2.4. **Microbiology Volumetric Equipment [TNI-EL-V1M5-2009-1.7.3.1.a.iii]**

Volumetric Equipment shall be calibrated as follows:

12.2.4.1. Equipment with movable parts such as automatic dispensers, dispensers/diluters, and mechanical hand pipettes shall be verified for accuracy quarterly.

12.2.4.2. Equipment such as filter funnels, bottles, non-class A glassware and other marked containers shall be calibrated once per lot prior to its use.

12.2.4.3. The volume of the disposable volumetric equipment such as sample bottles, disposable pipettes, and micropipette tips shall be checked once per lot.

12.2.5. **Glassware**

Table 12-2, contains the SOP for glassware cleaning. All class volumetric glassware is dried at room temperature rather than oven baked.

The washing and sterilization procedures for laboratory glassware are tested annually by testing glassware for inhibitory residues as shown in Standard Methods.

12.2.6. **Water Quality File**

The pure water system for EEA was assembled by US Filter in January 2003. It consists of reverse osmosis, mixed bed deionizers, ultraviolet disinfection, filtration, and an organic scavenger side stream return loop. The system is connected to a conductivity meter which signals when the mixed bed resin demineralizers need to be changed.

The quality of laboratory pure water is analyzed monthly for conductivity, pH, chlorine residual, TOC, and standard plate count and annually for water suitability ratio, inhibitory residue (annually, each time new lot of detergent and for new washing procedures), and trace metals (Pb, Cd, Cr, Cu, Ni, and Zn). Table 12-3 lists the acceptance criteria for these analytes. This data is recorded and submitted to the QA department. These reports are with the QA Department for review and maintained for ten years.

12.2.7. **Out of Service**

All major instruments if off line will be labeled “out of service” until repair.

12.3. PREVENTIVE MAINTENANCE

12.3.1. **Routine Maintenance Activities**

EEA carries maintenance contracts on all major laboratory equipment, under which much of the preventative maintenance is performed. Routine servicing, such as cleaning of rods, source, or detectors, is performed on a regular basis by the analyst. This type of service is performed according to the procedures and at the frequency specified by the manufacturer. Routine maintenance is done when instrument performance starts to degrade as demonstrated by a failure to meet one or more QC criteria, decreased ion sensitivity, degrading peak resolution, lowered response factors, or shifts in calibration curves. Activities that are performed on a routine basis can be found in the Instrument Maintenance Nonmethod14 SOP.

12.3.2. **Documentation**

Instrument maintenance logbooks are maintained for most major instruments. All repairs and any routine or non-routine maintenance activities are recorded in the logbooks. The date of the activity, the person performing it, and the nature of the activity are recorded. Expendable items for all major instruments are kept on hand to minimize downtime.

The following are documented in the instrument logbooks:

12.3.2.1. Name of the item of the equipment

12.3.2.2. Manufacturer’s name, type identification and serial number or other unique identification

12.3.2.3. Date received and date placed in service

12.3.2.4. Current location, where appropriate

12.3.2.5. Condition when received (e.g. new, used, reconditioned)

12.3.2.6. Copy of manufacturer’s instructions where available

12.3.2.7. Dates and results of calibrations and/or verifications and date of the next calibration and/or verification

12.3.2.8. Details of maintenance plan carried out to date and planned for the future

12.3.2.9. History of any damage, malfunction, modification or repair

12.3.2.10. Records of service calls

12.3.2.11. Calibration status for instrument that are calibrated outside the direct control of the laboratory are checked before use (after an instrument is returned from outside repair) [TNI-EL-V1M2-2009-5.5.9][ISO/IEC 17025:2005(E)-5.5.9].

12.3.3. **Contingency Plans**

12.3.3.1. An effort is made to have a functionally equivalent backup instrument available in case of a catastrophic instrument failure. Maintenance contracts are carried on the major instruments and generally provide for 24-48 hour response for repairs. If necessary, EEA has a list of qualified laboratories to subcontract work to, upon client approval.

12.3.3.2. In the event a holding time expires while the sample is in the custody of EEA, a project manager will call the client to inform them of this situation. Based on subsequent arrangements made between the lab and the client, fees for re-sampling and subsequent analysis may be incurred by the lab.

Table 12-1 Equipment (06/28/13)

Table 12-1 Equipment (06/28/13)

	Vendor	Model	Year Acquired	Detectors	Tests	Serial #

Table 12-2 Glassware Washing Procedures

Refer to the Nonmethod 16 SOP for detailed glassware cleaning procedures.

Table 12-3 Water Quality Parameters

Parameter	Acceptance Criteria
Ammonia	< 0.1 mg/L (monthly check)
Residual Chlorine	< 0.10 mg/L
TOC	< 1 mg/L
pH	5.5 - 7.5
EC	<2 µmhos/cm @ 25oC
	<2 µS (µsiemens/cm)
Trace Metals (Cd, Cr, Cu, Ni, Pb, Zn)	<0.05mg/L each collectively <0.1 mg/L
Bacteriological (HPC) Colony forming units/ml	<500 cfu (TNI < 10000 cfu/ml)
Bacteriological Quality of Reagent Water (Suitability Ratio or Ratio of Growth Rate)	0.8 - 3.00
Student’s t	< 2.78 for annual use test
Inhibitory Residue	<15% difference in average count

13.0 DOCUMENT MANAGEMENT/CONTROL OF RECORDS

13.1. ANALYTICAL DOCUMENTATION

A critical dimension of any quality assurance program is the ability to document what is occurring in the laboratory. Accordingly, EEA uses a number of forms to document various aspects of laboratory procedures. A discussion of these forms follows.

13.1.1. Analytical Data and Quality Control Forms

Printed forms are used by analysts to standardize the format of routine analyses. For analyses where forms are not available, the analyst records all required information in a notebook. The forms are designed to minimize calculation errors and provide a summary of all quality control data generated for the run.

Analysts are responsible for maintaining these forms. The QA group spot checks these forms periodically. These forms are actively maintained in hardcopy or electronically for a minimum period of 2 years and then stored electronically or stored in hardcopy offsite.

13.1.2. Chromatograms and Data Processing

Chromatograms and strip chart recordings are assigned unique alpha-numeric codes and backed-up on the server or an external hard drive. Information contained within the code includes; test, date and numerical sequence.

Computer records are stored by internal sample ID and test and therefore can be queried on this information.

Scanned hardcopy outputs of chromatograms and data processing are filed with the analytical data forms. Chromatograms and library searches are stored on magnetic tape and the information is retrievable upon client request.

13.1.3. Inventory Control Logs

Records are maintained on the purchase of laboratory supplies detailing the vendor, purchase order number, date of order, and date of receipt. Bottles of reagents are dated upon received so that the shelf life can be monitored.

13.1.4. Stock Standard Logs

A logbook is maintained for preparation of analytical stock standards for each group. Each log contains the date of fresh stock preparation, the lot number and supplier, the preparer's initials, and the weights used to prepare the stock.

13.1.5. Bacteriological Growth Media Log

Upon receipt of new microbiological media, the date received is noted upon the container. Media supplies are dated not only upon receipt but also when initially opened. A written record of quality control on media, materials, and equipment is logged into the Micro QC book. The record includes the results of the check, the initials of the individual performing the check, and the date. Media prepared in the lab is logged into the Prepared Media Log by the analyst. These records include media lot number, date of preparation, manufacturer and lot number, type and amount of media prepared, sterilization time and temperature, final pH, the analyst's initials, and expiration date.

13.1.6. Instrument Monitoring and Maintenance Logs

13.1.6.1. When in use, the operating temperatures of incubators, water baths, hot air ovens, and refrigerators are checked daily and recorded. Adjustments or service calls are made when required. Autoclave sterility checks, using ampules of bacterial spores, are made at least monthly, or whenever a problem is suspected but all items are autoclaved with sterility indicator tape. Records of the maintenance are maintained in equipment logs.

13.1.6.2. A separate maintenance logbook is maintained for each analytical instrument. These logs contain a record of routine maintenance as well as any repair work required during instrument set-up.

13.1.7. Corrective Action

The form, presented in Figure 15-2, requires documentation on the determination of the out-of-control event or variance, the diagnostics performed to bring the event back under control, and the manner in which re-establishment of control was demonstrated. A flow chart of QIR process can be found on Figure 15-3. The analyst and their supervisor sign the form electronically in STARLIMS and submit it to the QA department for review. Then, QA distributes the corrective action to the appropriate Project Manager so that the client may be contacted if necessary. The analysts keep hardcopies of original corrective action forms and file them with the appropriate raw data package.

13.2. CONTROL OF RECORDS

Figures 13-1 and 13-2 are examples of worksheets and notebooks used in data reduction.

13.2.1. General Records

13.2.1.1. The laboratory’s document control procedure includes identification, collection, indexing, access, filing, storage, maintenance and disposal of quality and technical records. Quality records include reports from internal audits and management reviews as well as records of corrective and preventive actions. Records are in the form of hard copy or electronic media.

13.2.1.2. All records are required to be legible and are stored and retained in such a way that they are readily retrievable in facilities that provide a suitable environment to prevent damage or deterioration and to prevent loss. Records are retained for 5 years held secure and in confidence as per TNI-EL-V1M2-2009-4.13.1.3 and 4.13.3.b (ISO/IEC 17025:2005(E)-4.13.1.3 and 4.13.3.b), 10 years for Massachusetts, Hawaii, and New York samples.

13.2.1.3. The laboratory has implemented procedures to protect and back-up records stored electronically and to prevent unauthorized access to or amendment of these records by setting up level of security and/or designating appropriate personnel responsible for the security of the records.

13.2.1.4. The following information is documented as per TNI-EL-V1M2-2009-4.13.3.

13.2.1.4.1. The records include the identity of personnel involved in sampling, sample receipt, preparation, calibration, or testing.

13.2.1.4.2. All information relating to the laboratory facilities equipment, analytical test methods, and related laboratory activities, such as sample receipt, sample preparation, or data verification are documented.

13.2.1.4.3. The record keeping system facilitates the retrieval of all working files and archived records for inspection and verification purposes by setting format for naming electronic files.

13.2.1.4.4. All changes to records are signed or initialed by responsible staff. The reason for the signature or initials is clearly indicated in the records such as “sampled by”, “prepared by”, or “reviewed by”.

13.2.1.4.5. All generated data except those that are generated by automated data collection systems, are recorded directly, promptly and legibly in permanent ink [TNI-EL-V1M2-2009-4.13.3.g].

13.2.1.4.6. Entries in records are not obliterated by methods such as erasures, overwritten files or markings. All corrections to record keeping errors are made by one line marked through the error. The individual making the correction signs (or initials) and date the correction. These criteria also apply to electronically maintained records [TNI-EL-V1M2-2009-4.13.2.3, 4.13.3.g.i (ISO/IEC 17025:2005(E)-4.13.2.3, 4.13.3.g.i). The laboratory keeps correspondence relating to lab activities for specific projects. Documentation includes email correspondence between the Project Manager and client.

13.2.2. **Technical Records**

13.2.2.1. The laboratory retains technical records of original observations, derived data and sufficient information to establish an audit trail, calibration records, staff records and a copy of each test report issued, for a defined period. The record for each environmental test or calibration contains sufficient information to facilitate and to enable the environmental test to be repeated under conditions as close as possible to the original. The records include the identity of personnel responsible for the performance of each environmental test and checking of results.

13.2.2.2. Observations, data and calculations are recorded at the time they are made and are identifiable to the specific task.

13.2.2.3. When mistakes occur in records, each mistake is crossed out, not erased, made illegible or deleted, and the correct value entered alongside. All such alterations to records are initialed and dated by the person making the correction. In the case of records stored electronically, equivalent measures are taken to avoid loss or change of original data. When corrections are due to reasons other than transcription errors, the reason for the correction shall be documented [TNI-EL-V1M2-2009-4.13.3.g.ii].

13.2.2.4. Each report or documents issued shall include the name(s), function(s) and signature(s) or equivalent electronic identification of person(s) authorizing the report or documents, and date of issue. Use of computer password unique to each analyst and level of security prevents loss of original data and change of data.

13.3. DATA STORAGE

13.3.1. EEA maintains electronic report files for at least 10 years. The report files are organized alphabetically by client and contain a copy of the report sent to the client, custody information and scheduling information. Report files also include subcontractor reports. The scannable supporting raw data is scanned within six months and stored electronically in the EEA secured server. The non-scannable data (i.e. hardbound logbooks) are stored in a secured offsite storage for a total of 5 years for all states, except 10 years for Hawaii, Massachusetts, and New York. These files are centrally located and a custodian is assigned to maintain, retrieve, and copy files as needed.

13.3.2. Instrument raw data is stored on each instrument's computer. Data is backed-up to a network server or an external hard drive (Chromeleon is backed up to the network server and GCMS/LCMS is backed up to an external hard drive. If instruments are direct read and transcribed into notebooks, then the notebooks are stored in the lab until they are scanned and filed.

13.3.3. All raw data is organized by instrument or test, then chronologically. Logbooks such as sample custody or balance calibration are organized chronologically.

13.3.4. Electronic data from LIMS is stored on data tapes.

13.4. DOCUMENT CONTROL

13.4.1. Document Control procedures are implemented that allow for adequate documentation and control of specific documents. These procedures use a unique identification system that allows for tracking, training documentation, traceability of official copies and the time period the procedure or document was in force. Documents issued to all personnel in the laboratory as part of the Quality System (QS) shall be reviewed and approved for use to authorized personnel prior to use. The list will identify the current revision status to ensure that invalid or obsolete documents are not used. The document control procedures includes that the authorized editions of documents are accessible by the analysts and invalid or obsolete documents are promptly removed from use. All QS documents such as SOP, QM, logbooks are uniquely identified including the following:

- Date of issue and/or revision ID
- Page numbering
- Total number of pages or markings to signify end of documents.
- Issuing authorities [TNI-EL-V1M2-2009-4.3.3.1][ISO/IEC 17025:2005(E)-4.3.3.1]

13.4.2. To ensure that the QM and SOPs remained controlled documents, the master SOPs and QM (original official version of the SOP and QM) and copies of the SOP and QA Manual will be identified. The cover page of each copy will contain a unique identification indicating that the document is controlled copy ___ of ____ copies, initialed and dated by the Quality Manager or her designee in red ink. This ensures that the analyst is currently using the right update or version.

13.4.3. A SOP/Quality Manual Distribution Form will be prepared for each SOP/QM that will include the SOP/QM ID, control number, individual receiving the SOP/Quality Manual, and date of issue.

13.4.4. Record management system is also implemented for control of laboratory notebooks; instrument logbook; standard logbook; and records for data reduction validation storage and reporting. Laboratory archival system will also be implemented to laboratory books and logbooks.

13.4.5. Notebooks and Logbooks are assigned unique ID numbers for control of laboratory records. Upon completion of the book, the analyst returns the book to QA. A new number is assigned to the newly issued notebook. See Table 13-1 for the laboratory document control system for notebooks and logbooks.

13.4.6. Changes to documents shall be reviewed and approved by the same function that performed the original review unless specifically designated otherwise. The designated personnel shall have access to pertinent background information upon which to base their review and approval. Refer to the Nonmethod 25 SOP for detailed document control procedures.

13.5. DOCUMENT CHANGES TO CONTROLLED DOCUMENTS

13.5.1. All documents and/or changes issued to personnel in the laboratory are reviewed and approved for use by the Lab Director, Technical Director and Quality Manager prior to use. A master list or an equivalent document control procedure identifying the current revision status and distribution of documents in the laboratory are established and are readily available to preclude the use of invalid and/or obsolete documents.

13.5.2. Any changes/alterations to laboratory documents are tracked and properly identified. Amendments are clearly marked, dated and initialed and revised documents are formally re-issued immediately. Any obsolete documents are removed from corresponding binders are archived and stored in a secured place.

13.6. ARCHIVAL SYSTEM

An archival system is implemented for managing and removal of all outdated documentation. Records that are archived are Training Records for personnel no longer with the laboratory and Outdated Quality Manual/SOPs. Only current versions of the Quality Manual/SOPs are retained in the laboratory areas. All outdated versions of the Quality Manual/SOPs are returned to the Quality Manager for archiving. All outdated logbooks/work books are turned in to the supervisor for scanning and archiving. Please see 13.3.1 for more information. Refer to the Nonmethod 30 SOP for archiving procedures.

13.7. STANDARD OPERATING PROCEDURES (SOP)

13.7.1. Laboratories shall maintain SOPs that accurately reflect all phases of current laboratory activities such as assessing data integrity, corrective actions, and all test methods.

13.7.2. When an amendment to the SOP is needed, such as a minor update to the entire procedure, the laboratory will handwrite the update with initials and date of the person who made the change in the original copy of the SOP. Also, when a minor mistake is found in the SOP, the laboratory will strike the section with one line, date and initials of the person who does the change in the original copy of the SOP. For any of these minor updates, the analyst(s), supervisor and QA will be notified and they will be included in the next update of the SOP.

13.7.3. The following format must be used for all final technical SOPs.

13.7.3.1. **Header** - A header must be included in the upper right corner of each page of the SOP. The header must include the SOP reference name or number, the revision number, the date the revision began, page number and total number of pages.

13.7.3.2. **Cover Page -** The SOP cover page consists of a summary of the most recent revision information and the signatures of the Analyst, Technical Manager/Group Supervisor, Quality Manager, and Technical Director/Lab Director stating that they approved the SOP including the date that they read and signed the SOP. The approval, issue, and effective dates are included on the cover page. The effective date is two weeks after the approval date.

13.7.3.3. **Body**

13.7.3.3.1. **Title**

13.7.3.3.2. **Scope and Application** - A brief description of the types of matrices the method is applicable to as well as the regulatory programs that may be supported by the use of the method. This section is also used to indicate any special training or level of ability required to perform the method.

13.7.3.3.3. **Method Summary** - A brief description of the method, simple statement of analytical technique and any pre-treatment steps.

13.7.3.3.4. **Interferences** - This section should include any known interferences, as well as potential interferences, particularly for GC/conventional detector methods. It should also include any interferences that may be present as a result of improper sampling procedures, equipment cleaning or analytical technique must be listed here.

13.7.3.3.5. **Safety Considerations** - Specify any known or suspected carcinogens, mutagens, or teratogens among the standards or reagents used. Indicate that the SDS (safety data sheets) are available and where they are located. Each analyst is required to familiarize him/herself with the contents of the SDS before performing the analysis.

Each SOP includes reference to the Laboratory Chemical Hygiene Plan as per OSHA Standard 29 CFR 1910.1450, Occupational Exposure to Hazardous Chemicals in Laboratories-Final Rule.

13.7.3.3.6. **Instrumentation/Apparatus** - The instrumentation used, including specific columns employed for GC, LC, or GC/MS and whether or not there is a primary and confirmatory column.

13.7.3.3.7. **Reagents and Standards** - The sources of all standards and reagents are listed.

13.7.3.3.8. **Sample Collection, Preservation and Handling** - Indicate bottle type, preservative and volume necessary for analysis. Include holding times for standards.

13.7.3.3.9. **Calibration Procedure** - Detailed preparation instructions for each calibration, LCS or MS/MSD standard should be included. A table should be present to show how daily calibration and control standard solutions are prepared from working stock standards. Calibration frequency should be specified. Expiration information should be included for each type of standard prepared.

13.7.3.3.10. **Analytical Procedure** - Since the purpose of a SOP is to provide clear instruction to avoid loss of key information from one analyst to another, it is critical that this section be detailed enough that any analyst can anticipate and take appropriate corrective action in the event that a problem should arise.

13.7.3.3.11. **Quality Control Requirements** - This section should describe the components, concentrations, frequency, and acceptance criteria for the LCS or MS/MSD samples, as well as any other method specific QC requirements, such as tuning, blanks, or calibration requirements.

13.7.3.3.12. **Calculations** - All relevant calculations should be included, such as how instrument response relates to concentration, the calculation of response factors, etc.

13.7.3.3.13. **Method Performance** - The results of the initial method validation process should be included. The following information should be present:

- Statistically calculated MDLs (40 CFR Part 136 Appendix B),
- MDL spike levels, EEA’s MRLs, Accuracy for each compound (mean recovery of each compound determined from analysis of a minimum of 4 replicates spiked at 1-4x MRL (TNI-EL-V1M4-2009-1.6.2.2.a) when method does not specify the spike level for the IDC study), precision data (RSD of the 4 replicates).

13.7.3.3.14. **References** - A list of method references, such as the relevant 500 or 600 series method, the SW-846 methods (including revision number and date), or Standard Methods should be provided.

13.7.3.3.15. **Deviations from Referenced Methodology** - A review of the referenced method is carefully made and EEA will specify any areas in which our method does not conform to referenced method requirements. If any such deviations are noted, an explanation as to what alternative was used and why is described. There are two basic types of method modifications: (1) those that are hardware related and (2) those that are policy or procedural modifications.

13.7.3.3.16. **Method Detection Limit** - Laboratory procedures of conducting MDL studies and a copy of the initial MDL study will be included.

13.7.3.3.17. **Demonstration of Capability** - Laboratory procedures of conducting DOC studies and a copy of the initial DOC study will be included.

13.7.3.3.18. **Definitions** - Definitions will be referred to the Quality Manual since the Quality Manual includes a glossary section that defines all the terms used by the laboratory.

13.7.3.3.19. **Pollution Prevention** - Potential threat of the standards and reagents to the environment is addressed in the SOP.

13.7.3.3.20. **Waste Management** - In addition to the hazardous waste protocol discussed in the SOP, the following references where the information can be find are also included:

- The Lab Hazwaste Management Plan
- The federal hazardous waste management regulations –Resources Conservation and Recovery Act (RCRA)-Title 40 of the Code of Federal Regulations, Parts 260 through 270 (40 CFR 260-270)
- CA Hazardous Waste Control Law (HWCL)-CCR Title 22 where 40 CFR was duplicated into CCR Title 22

13.7.3.3.21. **Revisions** - Revisions are discussed including the dates when revisions are made and the appropriate section numbers where the revisions could be found.

13.7.3.3.22. **Attachments** - A copy of the bench sheet used for the analysis and where applicable, an example chromatogram of the standards, calculations and any other relevant attachments.

14.0 DATA REDUCTION, VALIDATION, AND REPORTING

The process of transforming raw analytical data into a finished report involves steps which are generally grouped into the categories of data reduction, data validation, and reporting. It involves mathematical modeling of the standard calibration curves, statistical analysis of the acquired data, calculations to account for preparation steps and dilution, verification of adherence to quality assurance procedures, and the generation of hardcopy output.

14.1. DATA REDUCTION

At EEA the analyst performing an analysis has the primary responsibility for reducing raw data. This process consists of converting raw data values into final, reportable values by comparing individual sample results to those obtained for calibration purposes and then accounting for any dilution or concentration procedures.

The extent to which raw data from the instrument needs to be mathematically processed varies depending on the analysis. For the following methods finished data is directly read from the instrument; pH, conductivity, spectrophotometric/colorimetric measurements (i.e.: Chemical Oxygen Demand (COD), Chromium VI, phenols, phosphorus, Methylene Blue Activated Substances (MBAS, or commonly known as surfactants), odor and presence/absence bacteriological tests. Other methods require mathematical calculations and in some cases, such as for pesticides by GC, qualitative assessment of actual presence.

Below is an outline of the data reduction techniques used by technology.

14.1.1. <u>GC AND GC/MS</u>

A data reduction software system is used to calculate target compound concentrations. These concentrations are calculated by multiplying the average response factor for the compound by the area count as determined by the instrument. Average response factors are determined through linear regression during initial calibration, and may only be used if the correlation criteria have been met. This assumes linearity of the calibration curve through the origin. If linearity is not established then a second order fit (logarithmic regression) may be used to determine response factors. Another alternative is to use single point calibration, which matches the area counts from a single calibration point to the area counts of the sample, upon which a sample concentration is determined. Single point calibration is rarely used.

In all cases data is reduced by the data reduction software. Programs for linear, logarithmic and single point calibrations are available on command. Sample dilution factors are entered into the data reduction software prior to analysis and calculated into the final result.

14.1.2. GC/MS

Reportable results are provided by the data reduction software for GC/MS analyses using linear average response factors, or 2nd order fits, as described, except for diluted samples. For diluted samples the result from the system is multiplied by the dilution factor. Reporting limits are adjusted manually as well.

All regressions and calibration calculations are performed by the system software.

14.1.3. METALS

ICP & ICPMS results are processed and transferred directly into the LIMS system. Dilution and calibration information is entered and processed by the ICP software prior to data transfer.

All other results are reportable directly off the system.

14.1.4. HPLC / IC / SPECTROPHOTOMETRIC / POTENTIOMETRIC

All results are reportable directly off the system software or directly read off instrument. The cell constant for the conductivity meter is 1. All samples and standards are allowed to come to room temperature prior to analysis. Temperature correction is not needed.

14.1.5. MICROBIOLOGY

The ability of an individual analyst to count colonies accurately shall be verified at least once per month, by having two or more analysts count colonies from the same plate on one positive sample. Counts must be within 10% difference to be acceptable [TNI-EL-V1M5-2009-1.7.3.2].

14.2. DATA VALIDATION

Upon completion of each analytical run, the analyst checks the raw data and QC to determine if the run is acceptable for submission. Data are entered into the LIMS either manually or by electronic data upload using files generated by data acquisition programs attached to instruments, which are then imported using the Data Capture Upload program (DCU) in STARLIMS. The data package is submitted to the Supervisor or Peer Analyst for review. The submitted package contains all relevant documentation such as chromatograms, instrument run logs, digestion logs, information about calibration or second source standards and reagents, other printed pages from the instruments, result summary sheets, and/or a checklist.
The Reviewer is responsible for verifying the validity of the data by determining if all quality control parameters have been analyzed and are within method acceptance limits, checking calculations, assessing the acceptability of chromatography, and addressing any inconsistencies in the data with the analyst. Deviations from the method should be

documented by the analyst and/or reviewer. The documentation should explain the deviation, any flags associated with the deviation and the acceptability of the data. The review includes a perusal of the supporting documentation to ensure that the documentation is present and is complete. Before the Reviewer or Validator approves the data in LIMS, data in the package is checked against the LIMS to ensure that there are no transcription errors, retests have been properly initiated, the appropriate flags have been added, and any comments regarding data/sample integrity have been added at the run/sample level.

When all results and calculations for a folder have been approved, an e-mail is sent to the Project Manager stating that the report has been released. The report components are merged and the entire package is reviewed by the project manager on-line. The electronic signature of the project manager is added to the cover page before the report is released to the client.

Any logbooks such as sample preparation, instrument maintenance, calibration, internal custody, and disposal are reviewed by the supervisor/manager of that group. Initials and date of review are written on the final page reviewed. The review will focus on completeness, accuracy, trends, opportunities for improvement, and compliance.

14.3. DATA REVIEW POLICY/CORRELATION OF RESULTS

All analytical data must be reviewed by a peer analyst qualified in that analysis or the group supervisor. Supervisors are ultimately responsible for the quality of reported results. Data review includes the following:

14.3.1. Checking all QC data against the QC criteria.

14.3.2. All the sample calculations must be checked. Samples which are spot checked must be marked by the reviewing analyst.

14.3.3. The analytical run sheet must be signed by the primary analyst and the reviewing peer analyst. Changes to records must be signed and initialed by responsible staff [TNI-EL-V1M2-2009-4.13.2.3][ISO/IEC 17025:2005(E)-4.13.2.3].

14.3.4. All secondary reviewers or Supervisors must check all data sheets. For inorganics and metals they must verify data entry for those samples by checking the database. The secondary reviewer or Supervisor must initial each run sheet they review. For organics, the secondary reviewer or Supervisor must cross check all reports for transcription error from bench sheets.

14.3.5. All Supervisors or designee must validate the data reported into the computer system. The data validation group then reviews and validates the final reports electronically. The reports are then printed and reviewed by the Project Manager.

14.3.6. As part of the annual internal audits, the Quality Manager or QA staff must spot check data sheets to insure that the peer reviews are being performed and that review process is traceable to the peer review.

14.3.7. Correlation of results for different characteristics of a sample (example Total Phosphate ≥ Orthophosphate or TKN ≥ NH3 [TNI-EL-V1M2-2009-5.9.1.e][ISO/IEC 17025:2005(E)-5.9.1.e]

14.4. DATA REPORTING

To meet the TNI report requirement, the laboratory provides the following information in the final test report:

14.4.1. A Title

14.4.2. Name/address of laboratory

14.4.3. Phone number and name of contact person

14.4.4. Unique identification of the certificate or report and unique identification of each page, and the total number of pages

14.4.5. Name and address of client, where appropriate and project name if applicable

14.4.6. Description and unambiguous identification of the tested sample including the client identification code

14.4.7. Identification of results derived from samples that did not meet TNI acceptance requirements such as improper container, holding time, or temperature [TNI-EL-V1M2-2009-5.10.3][ISO/IEC 17025:2005(E)-5.10.3].

14.4.8. Date of receipt of sample, date and time of sample collection, date(s) of performance test, and time of sample preparation and/or analysis if the required holding time for either activity is less than or equal to 72 hours [TNI-EL-V1M2-2009-5.10.2][ISO/IEC 17025:2005(E)-5.10.2].

14.4.9. Identification of the test method used, or unambiguous description of any non-standard method used.

14.4.10. Qualification of numerical results with "E1-E7" flags or appropriate data flags for values outside the working range.

14.4.11. Any deviations from, additions to or exclusions from the test method, and any other information relevant to a specific test, such as environmental conditions including the use of relevant data qualifiers and their meaning.

14.4.12. Measurement, examinations and derived results and identification of any failures (such as failed quality control). Radiochemistry results shall be reported with associated measurement uncertainty [TNI-EL-V1M6-2009-1.7.2.4.b].

14.4.13. Identification whether the data are calculated on dry weight or wet weight, reporting units and when required by method a statement of the estimated uncertainty of the test result.

14.4.14. Signature and title of the person(s) accepting responsibility for the content of the report and date of issue.

14.4.15. Clear identification of all data provided by outside sources (subcontracted laboratories, clients, Non-NELAP accredited work, etc.)

14.4.16. Clear indication of numerical results with values outside of quantitation limits. Test results provided by subcontracted laboratories are identified by subcontractor name or applicable accreditation number.

When the validation steps are completed, and the managers and supervisors have keyed in their initials in the appropriate LIMS field to reflect this, the report number is automatically transferred to an electronic listing in LIMS. Reports on this list are printed out daily. The reports are reviewed for correctness against the data in LIMS and signed off by the project manager prior to being copied for the files and delivery to the client. An example of an analysis report form is shown in Figure 14-1. A sample of a QC Report is shown in Figure 14-3. After the report is issued to the client, the laboratory reports remain unchanged. The report shall not be reproduced except in full, without the written approval of the laboratory [TNI-EL-V1M2-2009-5.10.2] [ISO/IEC 17025:2005(E)-5.10.2]. After issue of report, material amendments to the test report is done in the form of further document or data transfer including the statement "Supplement to test report, group number _____". For EEA revised report, cover page – report # xxxxxx'r'. Comment, report # xxxxxx'r' replaces the original test report. Also, amendments to the formal report must meet all the TNI reporting requirements. The laboratory notifies clients in writing of any event such as the identification of defective measurement or test equipment that casts doubt on the validity of results given in any test report or amendment to a report [TNI-EL-V1M2-2009-4.14.5]. The laboratory also ensures that the TNI reporting requirements are met for test results transmitted by telephone, telex, facsimile or other electronic or electromagnetic means and that all reasonable steps taken to preserve client confidentiality. Final laboratory report includes a statement in the cover page "Laboratory certifies that the test results meet all TNI requirements unless noted in the comments section or the Case Narrative".

If Client requires monthly reports of data that does not include all items listed in 14.4, the laboratory is still required to provide all information in standard TNI report format required by the Client for use in preparing such regulatory reports [TNI-EL-V1M2-2009-5.10.1] [ISO/IEC 17025:2005(E)-5.10.1].

Copies of all client reports are filed electronically in a centralized server by year and client name. Scanned files are maintained for 5 years, except Massachusetts, Hawaii, and New York clients which are maintained for 10 years.

14.5. ELECTRONIC TRANSMISSION OF RESULTS

In the case of transmission of environmental test results by telephone, facsimile or other electronic means, the laboratory ensures preservation of Client confidentiality by attaching a cover page that includes the following statement:

> "This transmission and/or attachments contain information which is confidential and/or privileged. The information is intended for the addressee only. If you are not the intended recipient, any dissemination, distribution or copying of this communication is prohibited. If you have received this communication in error, please notify and return the original communication to the sender" [TNI-EL-V1M2-2009-5.10.5, 5.4.7.2.b] [ISO/IEC 17025:2005(E)-5.10.5, 5.4.7.2b].

14.6. GOOD AUTOMATED LABORATORY PRACTICES (GALP)

The laboratory assures that all requirements of the TNI and ISO 17025 standards are complied with where computers or automated equipment are used for the capture, processing, manipulation, recording, reporting, storage or retrieval of test data.

Section 8.1 through 8.11 of the EPA document 2185 – GALP is adopted by the laboratory for its computer use even though GALP is not required by TNI standard requirements. The laboratory ensures that the computer software is adequate for use and documented. To protect the integrity of data entry or capture, data storage, data transmission and data processing, the laboratory establishes and implements procedures in compliance to good automated laboratory practices. In addition, appropriate procedures are established for computer and automated equipment to ensure proper functioning and are provided with the environmental and operating conditions necessary to maintain the integrity of calibration and test data. Also the laboratory establishes and implements appropriate procedures for the maintenance of security of data including the prevention of unauthorized access to and the unauthorized amendment of computer records. The laboratory LIMS system provides several levels of security. The first level is the entry of a password to initially log on to the computer, then the person must be designated as a qualified user of STARLIMS. Additionally, the department to which a person is assigned governs accesses to the various functions of the system. The system also provides for read – only access to results to further protect the data from unauthorized modification or deletion. See laboratory GALP SOP for the Implementation of Good Automated Laboratory Practices. Implementation of the GALP includes data point comparison and manual calculations to test LIMS accuracy to be done during the data package review by the Quality Assurance Unit (QAU) (QM section 16.1.2). LIMS Audit Report form will be completed to document results of the LIMS audit. The laboratory QA group will ensure that all corrective actions are done when deficiencies are observed.

14.7. STATE SPECIFIC REPORTING REQUIREMENTS

Massachusetts – All analytes that are reported to the state of Massachusetts must have a means to distinguish between the analytes for which EEA is certified, and the analytes for which EEA is not certified. To meet this requirement, EEA only sends final reports to the Massachusetts Department of Environmental Protection the analytes for which EEA is certified in Massachusetts. Please see section 3.9 for more information about the certifications that EEA holds.

14.8. MCL NOTIFICATIONS

At approximately 10pm each night the Laboratory's STARLIMS software runs a report called a "Hits Report". This report is sent to all Project Managers. Part of the information in this report is a notification of any hits that exceed MCL levels for all client samples analyzed and approved since the last Hits Report. The Project Manager is responsible for notifying their clients of any exceedance within 24 hours of obtaining valid data. Since the report is sent to all Project Managers, absent PMs will have their client's data checked by their backups in order to ensure that no notifications are missed.

Please see Section 3.10.9 of this QM for the requirements on notification for subcontracting clients.

15.0 CONTROL OF NON-CONFORMING WORK, CORRECTIVE ACTION, AND PREVENTIVE MEASURES

Corrective actions may be required when there is a failure to meet quality control acceptance criteria, or when internal or external audit samples are not acceptable. Quality control measures for which control limits are established and maintained include: LCS, duplicates, method blanks, surrogate recoveries, MS/MSD, MRLs, calibrations, continuing calibrations and sensitivity checks. Refer to the Nonmethod 28 SOP for Non-conforming work procedures.

15.1. CORRECTIVE ACTION PROCEDURES, BY METHOD

Specific corrective actions on a method-by-method basis can be found in the Table 15-1. This SOP lists the processes and flags used to qualify data for submittal to clients. Corrective action will be initiated as a result of findings from internal or external audits, not acceptable results from performance samples, large variation from split samples and inadequate quality as determined by data validation review.

15.2. CORRECTIVE ACTION PROCEDURES, ROOT CAUSE, PREVENTIVE MEASURES, DATA QUALIFIERS, AND REPORT COMMENTS

15.2.1. Selection and Implementation of Corrective Actions

Failure to meet criteria of the LCS, surrogate spikes, internal standards, continuing calibration standards, holding time exceedance, improperly preserved samples, method blank contamination are QC failures that trigger the generation corrective actions to identify the root cause of the problem. Root causes of the problem are documented in the Quality Investigation Report (QIR).

For instance, when a matrix spike failure occurs during trace metals analysis, the analyst first checks the %RSD for the multiple measurements to see if the %RSD is less than 20%. Then the calibration verification will be checked along the calibration blank, preparation blank, and the second source LCS standard recovery. The standards and reagents preparation and expiration dates are reviewed. Spiking solutions are verified to ensure that here are no errors made in calculations and in spiking. If the MS/MSD recoveries are outside the internal QC limits and all the associated QCs for the batch are acceptable, the RPD for MS/MSD recoveries should be checked. If the RPD is found to be within the 20% criteria, the unacceptable recoveries are annotated in the report as suspect due to matrix effect. If the concentration of the background is much higher than the spiking amount the report will be annotated also. If the RPD is outside the limits, the sample that was spiked is checked visually to see if the sample is homogenous, if the sample is homogenous the batch will be reanalyzed.

15.2.2. Documentation of Corrective Actions

15.2.2.1. All corrective action taken for all QC failures is documented by generating a Quality Investigation Report (QIR). All other corrective action taken is documented on a Corrective Action Report (CAR). See Figure 15-2 for an example QIR.

Additional information is documented about the QC failures in the bench by the analyst.

15.2.2.2. Results are flagged not only for quality control failures where QIRs have been generated but also for all other QC failures that have impact on the data quality of the result. All results are flagged if data is suspect or QC was not acceptable.

15.2.2.3. Data qualifiers are used by the laboratory in reporting analytical results to flag the user about the data. Some of the qualifiers below were requested by a specific client as required in the Project's Quality Assurance Plan to ensure that the Data Quality Objectives of the project are met.

15.2.2.4. Comments on the results are provided to the clients on the final report for QC nonconformance. In addition, any QC data exceeding QC acceptance criteria are underlined to flag the user about the QC failure and its impact to the data quality of the associated samples in the batch.

15.2.2.5. Depending on the significance of nonconformance, the Client is notified by the Project Manager and work recalled if necessary [TNI-EL-V1M2-2009-4.9.1.d] [ISO/IEC 17025:2005(E)-4.9.1.d]. The Client is notified immediately for possible re-sampling.

15.2.2.6. Where the identification of nonconformance or departure casts doubts on the laboratory's compliance with its own policies and procedures, or on its compliance with this Standard, the laboratory shall ensure that the appropriate areas of activity are audited [TNI-EL-V1M2-2009-4.11.5][ISO/IEC 17025:2005(E)-4.11.5].

15.2.3. **Monitoring of Corrective Action**

15.2.3.1. Corrective actions implemented are monitored if corrective actions are effective to remove problem [TNI-EL-V1M2-2009-4.11.4][ISO/IEC 17025:2005(E)-4.11.4].

15.2.3.2. QA monitors CARs and QIRs for trends and notifies the analyst and supervisor of the need to correct the problem and implement corrective action to prevent the problem from reoccurring.

15.2.4. **Preventive Measures**

15.2.4.1. QIRs require the analyst to document preventive measures to ensure that the problems will not re-occur [TNI-EL-V1M2-2009-4.12.1][ISO/IEC 17025:2005(E)-4.12.1].

15.2.4.2. Preventive action, rather than corrective action, aims at minimizing or eliminating inferior data quality or other non-conformance through scheduled maintenance and review, before the non-conformance occurs. Preventive action is generated when circumstances are identified where a quality failure or non-conformance is a possibility or where an opportunity is identified to strengthen the quality system.

15.2.4.3. Preventive action includes, but is not limited to, review of QC data to identify quality trends, regularly scheduled staff quality meetings, annual managerial reviews, running a new LIMS in tandem with the old system to assure at least one working system, and other actions taken to prevent problems.

15.2.4.4. All staff recommends preventive action procedures to the Quality Manager and management is responsible for implementing preventive action.

15.2.4.5. A preventive action record form is generated when an opportunity for improvement arises to record preventive action, record actions generated, and ensure actions are effective. See Figure 15-2 for the Preventive Action Form which is used to document actions required for improvement, name of requestor, responsible personnel to carry out implementation, and estimated completion date.

15.3. ESTABLISHING WARNING/ACTION LIMITS

The incorporation of quality control samples and reference materials into the laboratory quality control program is of little use in maintaining overall analytical quality control unless the laboratory has established acceptance criteria for these samples. Quality control samples falling outside of these criteria serve as flags to signal the production of unacceptable data which must be rerun or reported as suspect data if re-running is not an option due to expired holding times or lack of sample volume.

15.3.1. Approach to Setting Limits

For methods that do not specify acceptance limits, the lab establishes limits through control charts. These limits should be updated once a year. These limits are based upon historical recoveries of LCS samples associated with specific matrices (or where LCS samples are not utilized, they are based on spike recoveries or duplicate limits for matrix specific samples).

For those cases where insufficient historical information exists to set statistically meaningful LCS or matrix specific limits, EEA has set limits based on the expected performance of the analysis until historical limits can be calculated. These limits are then associated with specific control requirements to determine out of control events.

15.3.2. <u>Documentation of Limits</u>

15.3.2.1. Reagent Blanks - Reagent blank values must remain lower than the reported MRL (some methods require ½ or 1/3 MRL) for each analytical procedure. If an analyst notices an increase in the reagent blank which is beginning to approach this limit, the source of contamination must be investigated before further analyses are performed.

15.3.2.2. External Reference Samples - Recoveries on external reference samples must fall within the acceptance limits provided with the true values.

15.3.2.3. Internal and Surrogate Standards - As specified by the methods, internal standards are run with each of the calibration standards and the area counts are recorded on the same form as the response factors. Any standard that has an internal standard area count beyond ±50% of the average internal standard area count for all initial calibration standards must be rerun to meet these criteria. Any sample with an internal standard count beyond ±50% (or as stated in the particular SOP) of the average internal standard counts for the ICAL standards must be rerun. Surrogate standards must meet the recovery limits specified in the analytical method or established historical limits, which are updated periodically.

15.3.2.4. Blind Check Samples - The results of blind check sample analyses must fall within the acceptance criteria provided with the samples.

15.3.3. <u>LCS Control Limits</u>

EEA uses method acceptance limits for LCS limits in water matrix to assess analytical control. All analysts have received a copy of these acceptance limits and must ensure that their LCS sample results fall within the stated acceptable ranges. If specific control limits have not been provided for matrix spikes or duplicates, LCS criteria are used until sufficient data is generated to calculate historical limits for the MS/MSD samples for a particular matrix. Any samples associated with unacceptable LCS samples must be re-run unless other criteria are available to allow acceptance of the data without qualification. If a sample cannot be rerun due to exceeded holding times or lack of sufficient sample volume or weight, then the data must be qualified as estimated when reported to the client.

15.4. CONTROL CHARTS

EEA collects LCS and MS/MSD data in the LIMS computer system for generation of control chart data and limits. Data can be downloaded and plotted on charts to determine trends, which may indicate problems with the analysis, or out of control events.

EEA utilizes a Shewhart mean chart modified to percent recovery to monitor laboratory control sample bias. This procedure is referenced in the EPA Handbook for Analytical

Quality Control in Water and Wastewater Laboratories (EPA-600/4-79-019), March 1979, on pages 6-2 to 6-6. Precision is monitored with control charts, but is compared to absolute limits established by the lab based on method specified limits.

Control charts for LCS and MS data are generated with the LIMS software periodically based on a maximum of 30 data points. The control chart limits are re-calculated at least annually. If analysis parameters are changed significantly or method modifications are performed, control chart limits may be re-calculated more frequently. QA reviews the limits and charts to determine whether any of the data is out-of-control. If the control charts indicate an out-of-control event, appropriate corrective action is immediately taken to bring the analysis back into control. An example of the Shewhart percentage recovery control chart is presented in Figure 15-4.

15.5. PROCEDURES FOR DETERMINING AND REPORTING OUT-OF-CONTROL ANALYSES

15.5.1. Defining an Out-of-Control Analysis

An analysis is out-of-control whenever a quality control sample or parameter falls outside of acceptance limits. Quality control parameters are evaluated for their acceptability on a daily basis according to established acceptance limits and are also monitored with control charts to detect trends in variability, which are indicative of a shift in the methodology due to analytical error.

15.5.1.1. Criteria Used

15.5.1.1.1. Daily Quality Controls

The quality control parameters utilized by EEA were detailed in Section 11.1. All of these controls are evaluated on a daily basis and must pass the criteria detailed in this section. Each analyst is familiar with the criteria for his/her analyses and is responsible for insuring that all quality control parameters on the analytical run are acceptable. An analyst cannot enter his/her data into the laboratory computer until the data is reviewed and approved by an appropriately trained peer or supervisor. In addition, LCS and MS/MSD data are also entered into the computer and linked to specific batches.

LCS and MS/MSD results must fall within given acceptance limits. These limits are provided for water matrix. Reagent blanks must remain below the MRL established for each parameter. External reference samples must fall within the acceptance criteria provided with the true values. Internal and surrogate standards must meet the recoveries specified in the analytical procedure, if historical control chart based information is not available. A new working standard must be checked against the old reference standard to verify its accuracy and must fall within 10% of its true value. If this agreement is not met, a referee standard must be run. All standards must be traceable to primary standards.

Instrument calibrations must fall within acceptance criteria in order for runs to proceed. Table 11-4 summarizes the instrument's initial calibration acceptance criteria for each analysis.

In addition to monitoring daily QC parameters for acceptability, control charts are utilized and interpreted as described in Section 15.4.

15.5.1.1.2. Approaches to Control Chart Interpretation

The control charts generated by the LIMS System flags the analyst that there is a potential problem whenever seven or more consecutive points fall above or below the mean.

If the above situation is observed, the cause of the shift in mean or increased variability must be investigated, corrected, and documented prior to analyzing any more samples.

15.5.2. <u>Responding to an Out-of-Control Event</u>

It is important to have an operational system within EEA for recognizing out-of-control events as soon as they occur so the appropriate action can be taken to bring the analysis back into control. This will insure that no data gets reported from a period when the analysis was out-of-control.

15.5.2.1. Roles and Responsibilities

The analyst has primary responsibility for verifying that all daily QC parameters fall within the acceptance limits before submitting the data for review. Review at the analyst level enables most errors to be caught immediately and prevents reporting delays. Following the analyst's verification, the data is reviewed by an appropriately trained peer analyst or supervisor. All of the quality control parameters are reviewed for compliance with the acceptance criteria and the calculations on the raw data forms are checked for errors in data manipulation. If the reviewer notices a problem, the analyst is notified immediately and corrective action is taken. All samples associated with unacceptable quality control samples are rerun unless there is insufficient sample, in which case the client is notified by the Client Services group [TNI-EL-V1M2-2009-4.9.1][ISO/IEC 17025:2005(E)-4.9.1]. Every out of control event must be documented by filing a Quality Investigation Report (QIR). See Figures 15-2 and Figure 15-3.

The check of daily QC parameters indicates immediate problems with the data, but trends are only evident on the control charts. Both the analyst and the Group

Supervisor are responsible for reviewing either the data or control charts for pattern to see if any of the out-of-control events summarized in Section 15.5.1 have occurred. If so, the analyst must initiate corrective action before continuing with the analysis.

15.5.2.2. Defining Suspect Samples

Sample data is considered suspect if associated with unacceptable MS/MSD and LCS samples or part of an analytical run that had an unacceptable calibration or an external reference sample was out of an expected range. GC/MS data is considered suspect if the internal or surrogate standards were not recovered within the acceptable range. Sample data is also considered suspect if the reagent blank has substantially increased beyond normal range and exceeds any of the compound MRL's.

15.5.2.3. Ensuring that Suspect Data Are Not Reported

It is the ultimate responsibility of the Group Leader to ensure that suspect data are not reported. The laboratory procedures currently require that analysts may not enter their final data into the computer until their analytical data form and accompanying QC parameters have been reviewed and approved by an appropriately trained peer or supervisor. The QA Group performs periodic system audits to ensure that this procedure is working properly and prepares reports to lab management based on these audits.

15.5.2.4. Corrective Action

15.5.2.4.1. If the calibration fails, the analyst must determine whether the problem lies with the standard, the reagents, or an instrument malfunctions. This is usually determined by reviewing all of the calibration QC parameters and determining which specific parameters do not meet the criteria. For example: 1) the regression statistics and recalculated standards look fine, 2) there was little drift during the run, 3) the peaks appear satisfactory, 4) the reagent blank is low, but 5) the external reference sample was out of range, it is likely that the problem lies with the integrity of the standard used to make up the working standards and a new stock standard should be prepared.

15.5.2.4.2. If calibration appears acceptable but some of the duplicate and spiked samples are unacceptable, the analyst must determine whether there is a matrix problem interfering with the analysis or the preparatory digestion. If all of the unacceptable duplicates and spikes occur on a specific type of matrix, this is good evidence that there is a matrix interference problem. When a preparatory digestion is part of the procedure, the problem can be isolated to the digestion or the instrumental analysis by comparing the LCS, which was carried through the digestion to a LCS sample analyzed without digestion. If a matrix problem is indicated, the analyst must determine the most appropriate procedure for alleviating the interference such as diluting the sample, using standard additions, performing the analysis at a different wavelength, using a different GC column, or modifying the digestion procedure.
